# Finding Closest Pair of Points

FIND CLOSEST

**Input:** Set  $S = \{(x_i, y_i) \mid x_i, y_i \in \mathbb{R}, \forall i \in [n]\}$ . We denote  $P_i = (x_i, y_i)$ .

**Question:** Given a set of points find the closest pair of points in  $\mathbb{R}^2$  find  $P_i, P_j$  that are at minimum  $l_2$  distance i.e. minimize  $\sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}$ .

## 1.1 Naive Algorithm

Now the naive algorithm for this will be checking all pairs of points and take their distance and output the minimum one. There are total  $\binom{n}{2}$  possible choices of pairs of points. And calculating the distance of each pair takes  $O(1)$  time. So it will take  $O(n^2)$  times to find the closest pair of points.

**Idea:**  $\forall P_i, P_j \in S$  find distance  $d(P_i, P_j)$  and return the minimum. Time taken is  $O(n^2)$ .

## 1.2 Divide and Conquer Algorithm

Below we will show a Divide and Conquer algorithm which gives a much faster algorithm.

### Definition 1.2.1: Divide and Conquer

- Divide: Divide the problem into two parts (roughly equal)
- Conquer: Solve each part individually recursively. If the subproblem sizes are small enough, however, just solve the subproblems in a straightforward manner.
- Combine: Combine the solutions to the subproblems into the solution.

### 1.2.1 Divide

So to divide the problem into two roughly equal parts we need to divide the points into two equal sets. That we can do by sorting the points by their  $x$ -coordinate. Suppose  $S^x$  denote we get the new sorted array of points. And similarly we obtain  $S^y$  which denotes the array of points after sorting  $S$  by their  $y$ -coordinate.

**Algorithm 1:** Step 1 (Divide)

---

```

1 Function Divide:
2   Sort  $S$  by  $x$ -coordinate and  $y$ -coordinate
3    $S^x \leftarrow S$  sorted by  $x$ -coordinate
4    $S^y \leftarrow S$  sorted by  $y$ -coordinate
5    $\bar{x} \leftarrow \lfloor \frac{n}{2} \rfloor$  highest  $x$ -coordinate
6    $\bar{y} \leftarrow \lfloor \frac{n}{2} \rfloor$  highest  $y$ -coordinate
7    $S^L \leftarrow \{P_i \mid x_i < \bar{x}, \forall i \in [n]\}$ 
8    $S^R \leftarrow \{P_i \mid x_i \geq \bar{x}, \forall i \in [n]\}$ 

```

---

**1.2.2 Conquer**

Now we will recursively get pair of closest points in  $S_L$  and  $S_R$ . Suppose the  $(P_1^L, P_2^L)$  are the closest pair of points in  $S^L$  and  $(P_1^R, P_2^R)$  are the closest pair of points in  $S^R$ .

**Algorithm 2:** Step 1 (Solve Subproblems)

---

```

1 Function Conquer:
2   Solve for  $S_L, S^R$ .
3    $(P_1^L, P_2^L)$  are closest pair of points in  $S_L$ .
4    $(P_1^R, P_2^R)$  are closest pair of points in  $S_R$ .
5    $\delta^L = d(P_1^L, P_2^L), \delta^R = d(P_1^R, P_2^R)$ 
6    $\delta_{min} \leftarrow \min\{\delta^L, \delta^R\}$ 

```

---

**1.2.3 Combine**

Now we want to combine these two solutions.

**Question 1.1: We are not done**

Is there a pair of points  $P_i, P_j \in S$  such that  $d(P_i, P_j) < \delta_{min}$

If Yes:

- One of them must be in  $S_L$  and the other is in  $S_R$ .
- $x$ -coordinate  $\in [\bar{x} - \delta_{min}, \bar{x} + \delta_{min}]$ .
- $|y_i - y_j| \leq \delta_{min}$

So we take the strip of radius  $\delta_{min}$  around  $\bar{x}$ . Define  $T = \{P_i \in S \mid |x_i - \bar{x}| \leq \delta_{min}\}$

We now sort all the points in the  $T$  by their decreasing  $y$ -coordinate. Let  $T_y$  be the array of points. For each  $P_i \in T_y$  define the region

$$T_i = \{P_j \in T_y \mid 0 \leq y_j - y_i \leq \delta_{min}, j > i\}$$

**Lemma 1.2.1**

Number of points (other than  $P_i$ ) that lie inside the box is at most 8

**Proof:** Suppose there are more than 8 points that lie inside the box apart from  $P_i$ . The box has a left square part and a right square part. So one of the squares contains at least 5 points. WLOG suppose the left square has at least 5 points. Divide each square into 4 parts by a middle vertical and a middle horizontal line. Now since there are 5 points there is one part which contains 2 points but that is not possible as those two points are in  $S_L$  and their distance will be less than  $\delta_{min}$  which is not possible. Hence contradiction. Therefore there are at most 8 points inside the box. ■

Hence by the above lemma for each  $P_i \in T_y$  there are at most 8 points in  $T_i$ . So for each  $P_j \in T_i$  we find the  $d(P_i, P_j)$  and if it is less than  $\delta_{min}$  we update the points and the distance

## 1.2.4 Pseudocode and Time Complexity

**Assumption.** We will assume for now that for all  $P_i, P_j \in S$  we have  $x_i \neq x_j$  and  $y_i \neq y_j$ . Later we will modify the pseudocode to remove this assumption

---

**Algorithm 3: FIND-CLOSEST( $S$ )**

---

**Input:** Set of  $n$  points,  $S = \{(x_i, y_i) \mid x_i, y_i \in \mathbb{R}, \forall i \in [n]\}$ . We denote  $P_i = (x_i, y_i)$ .

**Output:** Closest pair of points,  $(P_i, P_j, \delta)$  where  $\delta = d(P_i, P_j)$

---

```

1 begin
2   if  $|S| \leq 10$  then
3     Solve by Brute Force (Consider every pair of points)
4    $S^x \leftarrow S$  sorted by  $x$ -coordinate,    $S^y \leftarrow S$  sorted by  $y$ -coordinate
5    $\bar{x} \leftarrow \lfloor \frac{n}{2} \rfloor$  highest  $x$ -coordinate,    $\bar{y} \leftarrow \lfloor \frac{n}{2} \rfloor$  highest  $y$ -coordinate
6    $S^L \leftarrow \{P_i \mid x_i < \bar{x}, \forall i \in [n]\}$ ,    $S^R \leftarrow \{P_i \mid x_i \geq \bar{x}, \forall i \in [n]\}$ 
7    $(P_1^L, P_2^L, \delta^L) \leftarrow \text{FIND-CLOSEST}(S^L)$ ,    $(P_1^R, P_2^R, \delta^R) \leftarrow \text{FIND-CLOSEST}(S^R)$ 
8    $\delta_{min} \leftarrow \min\{\delta^L, \delta^R\}$ 
9   if  $\delta_{min} < \delta^L$  then
10      $P_1 \leftarrow P_1^R, P_2 \leftarrow P_2^R$ 
11   else
12      $P_1 \leftarrow P_1^L, P_2 \leftarrow P_2^L$ 
13    $T \leftarrow \{P_i \mid |x_i - \bar{x}| \leq \delta_{min}\}$ 
14    $T_y \leftarrow T$  sorted by decreasing  $y$ -coordinate
15   for  $P \in T_y$  do
16      $U \leftarrow$  Next 8 points
17     for  $\hat{P} \in U$  do
18       if  $d(P, \hat{P}) < \delta_{min}$  then
19          $\delta_{min} \leftarrow d(P, \hat{P})$ 
20          $(P_1, P_2) \leftarrow (P, \hat{P})$ 
21 return  $(P_1, P_2, \delta_{min})$ 

```

---

Notice we used the assumption in the line 5 for finding the medians. So the line 4 takes  $O(n \log n)$  times. Lines 5,6 takes  $O(n)$  time. Since  $\bar{x}$  is the median, we have  $|S^L| = \lfloor \frac{n}{2} \rfloor$  and  $|S^R| = \lceil \frac{n}{2} \rceil$ . Hence  $\text{FIND-CLOSEST}(S^L)$  and  $\text{FIND-CLOSEST}(S^R)$  takes  $T(\frac{n}{2})$  time. Now lines 8 – 12 takes constant time. Line 13 takes  $O(n)$  time. And line 14 takes  $O(n \log n)$  time. Since  $U$  has 8 points i.e. constant number of points the lines 16 – 20 takes constant time for each  $P \in T_y$ . Hence the for loop at

line 15 takes  $O(n)$  time. Hence total time taken

$$T(n) = O(n) + O(n \log n) + 2T\left(\frac{n}{2}\right) \implies T(n) = O(n \log^2 n)$$

### 1.3 Improved Algorithm for $O(n \log n)$ Runtime

Notice once we sort the points by  $x$ -coordinate and  $y$ -coordinate we don't need to sort the points anymore. We can just pass the sorted array of points into the arguments for solving the smaller problems. There is another time where we need to sort which is in line 14 of the above algorithm. This we can get actually from  $S^y$  without sorting just checking one by one backwards direction if the  $x$ -coordinate of the points satisfy  $|x_i - \bar{x}| \leq \delta_{min}$ . So

$$T_y = \text{REVERSE}(\{P_i \in S^y \mid |x_i - \bar{x}| \leq \delta_{min}\})$$

So we form a new algorithm which takes the input  $S^x$  and  $S^y$  and then finds the closest pair of points. Then we will use that subroutine to find closest pair of points in any given set of points.

---

**Algorithm 4:** FIND-CLOSEST-SORTED( $S^x, S^y$ )

---

**Input:** Set of  $n$  points,  $S = \{(x_i, y_i) \mid x_i, y_i \in \mathbb{R}, \forall i \in [n]\}$ .  
 $S^x$  and  $S^y$  are the sorted array of points with respect to  $x$ -coordinate and  $y$ -coordinate respectively

**Output:** Closest pair of points,  $(P_i, P_j, \delta)$  where  $\delta = d(P_i, P_j)$

```

1 begin
2   if  $|S| \leq 10$  then
3     Solve by Brute Force
4    $\bar{x} \leftarrow \lfloor \frac{n}{2} \rfloor$  highest  $x$ -coordinate
5    $\bar{y} \leftarrow \lfloor \frac{n}{2} \rfloor$  highest  $y$ -coordinate
6    $S^L \leftarrow \{P_i \in S^x \mid x_i < \bar{x}, \forall i \in [n]\}$ 
7    $S_y^L \leftarrow \{P_i \in S^y \mid x_i < \bar{x}\}$ 
8    $S^R \leftarrow \{P_i \in S^x \mid x_i \geq \bar{x}, \forall i \in [n]\}$ 
9    $S_y^R \leftarrow \{P_i \in S^y \mid x_i \geq \bar{x}\}$ 
10   $(P_1^L, P_2^L, \delta^L) \leftarrow \text{FIND-CLOSEST-SORTED}(S^L, S_y^L)$ 
11   $(P_1^R, P_2^R, \delta^R) \leftarrow \text{FIND-CLOSEST-SORTED}(S^R, S_y^R)$ 
12   $\delta_{min} \leftarrow \min\{\delta^L, \delta^R\}$ 
13  if  $\delta_{min} < \delta^L$  then
14     $P_1 \leftarrow P_1^R, P_2 \leftarrow P_2^R$ 
15  else
16     $P_1 \leftarrow P_1^L, P_2 \leftarrow P_2^L$ 
17   $T \leftarrow \{P_i \mid |x_i - \bar{x}| \leq \delta_{min}\}$ 
18   $T_y \leftarrow \text{REVERSE}(\{P_i \in S^y \mid |x_i - \bar{x}| \leq \delta_{min}\})$ 
19  for  $P \in T_y$  do
20     $U \leftarrow$  Next 8 points
21    for  $\hat{P} \in U$  do
22      if  $d(P, \hat{P}) < \delta_{min}$  then
23         $\delta_{min} \leftarrow d(P, \hat{P})$ 
24         $(P_1, P_2) \leftarrow (P, \hat{P})$ 
25  return  $(P_1, P_2, \delta_{min})$ 

```

---

---

**Algorithm 5:** FIND-CLOSEST( $S$ )

---

**Input:** Set of  $n$  points,  
 $S = \{(x_i, y_i) \mid x_i, y_i \in \mathbb{R}, \forall i \in [n]\}$ .  
We denote  $P_i = (x_i, y_i)$ .

**Output:** Closest pair of points,  $(P_i, P_j, \delta)$   
where  $\delta = d(P_i, P_j)$

```

1 begin
2   if  $|S| \leq 10$  then
3     Solve by Brute Force
4    $S^x \leftarrow S$  sorted by  $x$ -coordinate
5    $S^y \leftarrow S$  sorted by  $y$ -coordinate
6   return FIND-CLOSEST-SORTED( $S^x, S^y$ )

```

---

This algorithm only sorts one time. So time complexity for FIND-CLOSEST-SORTED( $S^x, S^y$ ) is

$$T(n) = 2T\left(\frac{n}{2}\right) + O(n) \implies T(n) = O(n \log n)$$

and therefore time complexity for FIND-CLOSEST( $S$ ) is  $O(n \log n)$ .

## 1.4 Removing the Assumption

For this there nothing much to do. For finding the median  $\bar{x}$  if we have more than one points with same  $x$ -coordinate which appears as the  $\lfloor \frac{n}{2} \rfloor$  highest  $x$ -coordinate we sort only those points with respect to their  $y$ -coordinate update the  $S^x$  like that and then take  $\lfloor \frac{n}{2} \rfloor$  highest point in  $S^x$ . We do the same for  $S^y$  and update accordingly. All this we do so that  $S^L$  and  $S^R$  has the size  $\frac{n}{2}$ .

# Median Finding in Linear Time

MEDIAN FIND

**Input:** Set  $S$  of  $n$  distinct integers

**Question:** Find the  $\lfloor \frac{n}{2} \rfloor^{th}$  smallest integer in  $S$

## 2.1 Naive Algorithm

The naive algorithm for this will be to sort the array in  $O(n \log n)$  time then return the  $\lfloor \frac{n}{2} \rfloor^{th}$  element. This will take  $O(n \log n)$  time. But in the next section we will show a linear time algorithm.

## 2.2 Linear Time Algorithm

In this section we will show an algorithm to find the median of a given set of distinct integers in  $O(n)$  time complexity. Consider the following two problems:

RANK-FIND ( $S, k$ )

**Input:** Set  $S$  of  $n$  distinct integers and an integer  $k \leq n$

**Question:** Find the  $k^{th}$  smallest integer in  $S$

APPROXIMATE-SPLIT( $S$ )

**Input:** Set  $S$  of  $n$  distinct integers

**Question:** Given  $S$ , return an integer  $z \in S$  such that  $z$  where  $rank(z) \in [\frac{n}{4}, \frac{3n}{4}]$

### 2.2.1 Solve RANK-FIND using APPROXIMATE-SPLIT

---

**Algorithm 6:** RANK-FIND( $S, k$ )

---

**Input:** Set  $S$  of  $n$  distinct integer and  $k \in [n]$

**Output:**  $k^{th}$  smallest integer in  $S$

```

1 begin
2   if  $|S| \leq 100$  then
3      $\lfloor$  Sort  $S$ , return  $k^{th}$  smallest element in  $S$ 
4    $z \leftarrow$  APPROXIMATE-SPLIT( $S$ )      ( $z$  is the  $r^{th}$  smallest element for some  $r \in [\frac{n}{4}, \frac{3n}{4}]$ )
5    $S_L \leftarrow \{x \in S \mid x \leq z\}$ ,  $S_R \leftarrow \{x \in S \mid x > z\}$ 
6   if  $k \leq |S_L|$  then
7      $\lfloor$  return RANK-FIND( $S_L, k$ )
8   return RANK-FIND( $S_R, k - |S_L|$ )

```

---

Certainly if we can solve  $\text{RANK-FIND}(S, k)$  for all  $k \in [n]$  we can also solve  $\text{MEDIAN-FIND}$ . We will try to use both the problems and recurse to solve  $\text{RANK-FIND}$  in linear time.

In the above algorithm  $\text{rank}(z) \in [\frac{n}{4}, \frac{3n}{4}]$ . So  $\frac{n}{4} \leq |S_L|, |S_R| \leq \frac{3n}{4}$ . For now suppose  $\text{RANK-FIND}(S, k)$  takes  $T_{RF}(n)$  time and  $\text{APPROXIMATE-SPLIT}(S)$  takes  $T_{AS}(n)$  time. Then the time taken by the algorithm is

$$T_{RF}(n) \leq O(n) + T_{AS}(n) + T_{RF}\left(\frac{3n}{4}\right)$$

### 2.2.2 Solve APPROXIMATE-SPLIT using RANK-FIND

We first divide  $S$  into groups of 5 elements. So take  $t = \lceil \frac{n}{5} \rceil$ . Now we sort each group. Since each group have constant size this can be done in  $O(n)$  time. So now consider the scenario:

After sorting each of the groups we take the medians of each group. Let  $z$  be the median of the medians. We claim that  $\text{rank}(z) \in [\frac{n}{4}, \frac{3n}{4}]$ .

---

#### Algorithm 7: APPROXIMATE-SPLIT( $S$ )

---

**Input:** Set  $S$  of  $n$  distinct integers  
**Output:** An integer  $z \in S$  such that  $\text{rank}(z) \in [\frac{n}{4}, \frac{3n}{4}]$

```

1 begin
2   if  $|S| \leq 100$  then
3     Sort, return Exact median
4    $t \leftarrow \lceil \frac{n}{5} \rceil$ 
5    $S_i \leftarrow i^{\text{th}}$  block of 5 elements in  $S$  for  $i \in [t-1]$ 
6    $S_t \leftarrow$  Whatever is left in  $S$ 
7   for  $i \in [t]$  do
8     Sort  $S_i$ , Let  $h_i$  be the median of  $S_i$ 
9    $T \leftarrow \{h_i \mid i \in [t]\}$ 
10  return  $\text{RANK-FIND}(T, \lfloor \frac{t}{2} \rfloor)$ 
```

---

So in the picture among elements in upper left the highest element is  $z$  and among the elements in lower right the lowest element is  $z$ . We will show that the number of elements smaller than  $z$  is between  $\frac{n}{4}$  and  $\frac{3n}{4}$ . Lets call the set of elements in upper left box is  $S_u$  and the set of elements in lower right box is  $S_d$ .

**Lemma 2.2.1**

$$|S_u|, |S_d| \geq \frac{n}{4}$$

**Proof:**  $|S_u| \geq 3 \times \lfloor \frac{t}{2} \rfloor$ . For  $n \geq 100$ ,  $3 \lfloor \frac{t}{2} \rfloor > \frac{n}{4}$ . Hence  $|S_u| \geq \frac{n}{4}$ . Now similarly  $|S_d| \geq 3 \lfloor \frac{t}{2} - 1 \rfloor \geq \frac{n}{4}$ . ■

**Lemma 2.2.2**

Number of elements in  $S$  smaller than  $z$  lies between  $\frac{n}{4}$  and  $\frac{3n}{4}$ .

**Proof:** Now number of elements in  $S$  smaller than  $z \geq |S_u| \geq \frac{n}{4}$ . The number of elements greater than  $z \geq |S_d| \geq \frac{n}{4}$ . So number of elements in  $S$  smaller than  $z \leq n - \text{number of elements greater than } z \leq n - \frac{n}{4} = \frac{3n}{4}$ . ■

Hence the APPROXIMATE-SPLIT( $S$ ) takes time

$$T_{AS}(n) = O(n) + T_{RF}\left(\frac{n}{5}\right)$$

**2.2.3 Pseudocode and Time Complexity**

Hence using APPROXIMATE-SPLIT the final algorithm for RANK-FIND is the following:

**Algorithm 8: RANK-FIND( $S, k$ )**

---

**Input:** Set  $S$  of  $n$  distinct integer and  $k \in [n]$   
**Output:**  $k^{th}$  smallest integer in  $S$

---

```

1 begin
2   if  $|S| \leq 100$  then
3      $\lfloor$  Sort  $S$ , return  $k^{th}$  smallest element in  $S$ 
4    $t \leftarrow \lceil \frac{n}{5} \rceil$ 
5    $S_i \leftarrow i^{th}$  block of 5 elements in  $S$  for  $i \in [t-1]$ 
6    $S_t \leftarrow$  Whatever is left in  $S$ 
7   for  $i \in [t]$  do
8      $\lfloor$  Sort  $S_i$ , Let  $h_i$  be the median of  $S_i$ 
9    $T \leftarrow \{h_i \mid i \in [t]\}$ 
10   $z \leftarrow \text{RANK-FIND}(T, \lfloor \frac{t}{2} \rfloor)$ 
11   $S_L \leftarrow \{x \in S \mid x \leq z\}$ ,  $S_R \leftarrow \{x \in S \mid x > z\}$ 
12  if  $k \leq |S_L|$  then
13     $\lfloor$  return  $\text{RANK-FIND}(S_L, k)$ 
14  return  $\text{RANK-FIND}(S_R, k - |S_L|)$ 

```

---

Replacing  $T_{AS}(n)$  in the time complexity equation of  $T_{RF}(n)$  we get the equation:

$$T_{RF}(n) \leq O(n) + T_{RF}\left(\frac{n}{5}\right) + T_{RF}\left(\frac{3n}{4}\right)$$

Let  $T_{RF}(n) \leq kn + T_{RF}\left(\frac{n}{5}\right) + T_{RF}\left(\frac{3n}{4}\right)$ . We claim that  $T_{RF}(n) \leq cn$  for some  $c \in \mathbb{N}$  for all  $n \geq n_0$  where  $n_0 \in \mathbb{N}$ . By induction we have

$$T_{RF}(n) \leq kn + \frac{cn}{5} + \frac{3cn}{4} = \left(k + \frac{19c}{20}\right)n$$

To have  $k + \frac{19c}{20} \leq c$  we have to have  $k + \frac{19c}{20} \leq c \iff c \geq 20k$ . So take  $c \geq 20k$  and our claim follows. Hence  $T_{RF}(n) = O(n)$ . Since we can find any  $k^{th}$  smallest number in a given set of distinct integers in linear time we can also find the median in linear time.

# Polynomial Multiplication

## POLYNOMIAL MULTIPLICATION

**Input:** Given 2 univariate polynomials of degree  $n - 1$  by 2 arrays of their coefficients  $(a_0, \dots, a_{n-1})$  and  $(b_0, \dots, b_{n-1})$  such that  $A(x) = a_0 + a_1x + \dots + a_{n-1}x^{n-1}$  and  $B(x) = b_0 + b_1x + \dots + b_{n-1}x^{n-1}$  respectively

**Question:** Given 2 polynomials of degree  $n - 1$  find their product polynomial  $C(x) = A(x)B(x)$  of degree  $2n - 2$  by returning the array of their coefficients.

### 3.1 Naive Algorithm

We can do this naively by calculating each coefficient of  $C$  in  $O(n)$  time since for any  $i \in \{0, \dots, 2n - 2\}$

$$c_i = \sum_{j=0}^i a_j b_{i-j}$$

Since there are  $2n - 1 = O(n)$  total coefficient of  $C$  it takes total  $O(n^2)$  time. In the following section we will do this in  $O(n \log n)$  time.

### 3.2 Strassen-Schönhage Algorithm

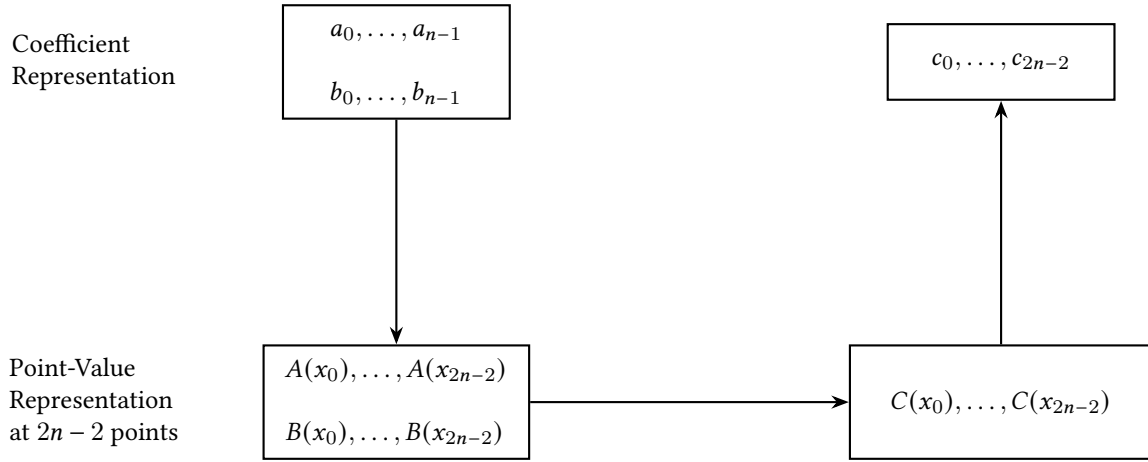

Before diving into the algorithm first let's consider how many ways we can represent a polynomial. Often changing the representation helps solving the problem in less time.

- **Coefficients:** We can represent a polynomial by giving the array of all its coefficient.
- **Point-Value Pairs:** We can evaluate the polynomial in distinct  $n$  points and give all the point-value pairs. This also uniquely represents a polynomial since there is exactly one polynomial of degree  $n - 1$  which passes through all these points.

#### Theorem 3.2.1

Given  $n$  distinct points  $(x_0, y_0), \dots, (x_{n-1}, y_{n-1})$  in  $\mathbb{R}^2$  there is an unique  $(n - 1)$ -degree polynomial  $P(x)$  such that  $P(x_i) = y_i$  for all  $i \in \llbracket n - 1 \rrbracket$

Since we want to find the polynomial  $C(x) = A(x)B(x)$  and  $C(x)$  has degree  $2n - 2$ , we will evaluate the polynomials  $A(x)$  and  $B(x)$  in  $2n - 1$  distinct points. So we will have the algorithm like this:

### 3.2.1 Finding Evaluations of Multiplied Polynomial

Suppose we were given  $A(x)$  and  $B(x)$  evaluated at  $2n-1$  distinct points  $x_0, \dots, x_{2n-2}$ . Then we can get  $C(x)$  evaluated at  $x_0, \dots, x_{2n-2}$  by

$$C(x_i) = A(x_i)B(x_i) \quad \forall i \in \llbracket 2n-2 \rrbracket$$

Since there are  $O(n)$  many points and for each point it takes constant time to multiply we can find evaluations of  $C$  at  $x_0, \dots, x_{2n-2}$  in  $O(n)$  time.

### 3.2.2 Evaluation of a Polynomial at Points

#### Question 3.1

Suppose there is only one point,  $x_0$ . Can we evaluate a  $n-1$  degree polynomial  $A(x) = \sum_{i=0}^{n-1} a_i x^i$  at  $x_0$  efficiently?

We can rewrite  $A(x)$  as

$$A(x) = a_0 + x(a_1 + x(a_2 + x(a_3 + \dots (a_{n-1} + x(a_n)) \dots)))$$

In this representation it is clear that we have to do  $n$  additions and  $n$  multiplications to find  $A(x_0)$ . Hence we can evaluate a  $n-1$  degree polynomial at a point in  $O(n)$  time.

But we have  $O(n)$  points. And if each point takes  $O(n)$  time to find the evaluation of the polynomial then again it will take total  $O(n^2)$  time. We are back to square one. So instead we will evaluate the polynomial in some special points and we will evaluate in all of them in  $O(n \log n)$  time. So now the problem we will discuss now is to find some special  $n$  points where we can evaluate a  $n-1$ -degree polynomial in  $O(n \log n)$  time.

**Idea:** Evaluate at roots of unity and use Fast Fourier Transform

Assume  $n$  is a power of 2. We have the polynomial  $A(x) = \sum_{i=0}^{n-1} a_i x^i$ . So now consider the following two polynomials

$$A^0(x) = a_0 + a_2x + a_4x^2 + \dots + a_{n-2}x^{\frac{n}{2}-1} \quad A^1(x) = a_1 + a_3x + a_5x^2 + \dots + a_{n-1}x^{\frac{n}{2}-1}$$

Certainly we have

$$A(x) = A^0(x^2) + xA^1(x^2)$$

Hence we can get  $A(1)$  and  $A(-1)$  by

$$A(1) = A^0(1) + A^1(1) \quad A(-1) = A^0(1) - A^1(1)$$

Hence like this by evaluating two  $\frac{n}{2}-1$  degree polynomials at one point we get evaluation of  $A$  at two points. More generally for any  $y \geq 0$  we have

$$A(\sqrt{y}) = A^0(y) + \sqrt{y}A^1(y) \quad A(-\sqrt{y}) = A^0(y) - \sqrt{y}A^1(y)$$

So by recursing like this evaluating at 1, -1 we can get evaluations of  $A$  at  $n^{th}$  roots of unity.

Let

$$\omega_n^k = n^{th} \text{ root of unity for } k \in \llbracket n-1 \rrbracket = e^{i \frac{k}{n} 2\pi} = \cos\left(\frac{k}{n} 2\pi\right) + i \sin\left(\frac{k}{n} 2\pi\right)$$

Hence we have

$$\begin{aligned} A(\omega_n^k) &= A^0(\omega_n^{2k}) + \omega_n^k A^1(\omega_n^{2k}) = A^0\left(\omega_{\frac{n}{2}}^k\right) + \omega_n^k A^1\left(\omega_{\frac{n}{2}}^k\right) \\ A(-\omega_n^k) &= A\left(\omega_n^{\frac{n}{2}+k}\right) = A^0(\omega_n^{2k}) - \omega_n^k A^1(\omega_n^{2k}) = A^0\left(\omega_{\frac{n}{2}}^k\right) - \omega_n^k A^1\left(\omega_{\frac{n}{2}}^k\right) \end{aligned}$$

Hence now we will solve the following problem:

RECURSIVE-DFT

**Input:**  $(a_0, \dots, a_{n-1})$  representing  $(n-1)$ -degree polynomial  $A(x) = \sum_{i=0}^{n-1} a_i x^i$

**Question:** Find the evaluations of the polynomial  $A(x)$  in all  $n^{th}$  roots of unity

Since  $A^0$  and  $A^1$  have degree  $\frac{n}{2} - 1$  we can use recursion. Hence the algorithm is

---

**Algorithm 9:** RECURSIVE-DFT( $A$ )

---

**Input:**  $A = (a_0, \dots, a_{n-1})$  such that  $A(x) = a_0 + a_1 x + \dots + a_{n-1} x^{n-1}$   
**Output:**  $A(x)$  evaluated at  $n^{th}$  roots of unity  $\omega_n^k$  for all  $k \in \llbracket n-1 \rrbracket$

```

1 begin
2   if  $n == 1$  then
3     return  $A[0]$ 
4    $A^0 \leftarrow (A[0], A[2], \dots, A[n-2])$ 
5    $A^1 \leftarrow (A[1], A[3], \dots, A[n-1])$ 
6    $Y^0 \leftarrow \text{RECURSIVE-DFT}(A^0)$ 
7    $Y^1 \leftarrow \text{RECURSIVE-DFT}(A^1)$ 
8   for  $k = 0$  to  $\frac{n}{2} - 1$  do
9      $Y[k] \leftarrow Y^0[k] + \omega_n^k Y^1[k]$  //  $A(\omega_n^k) = A^0\left(\omega_{\frac{n}{2}}^k\right) + \omega_n^k A^1\left(\omega_{\frac{n}{2}}^k\right)$ 
10     $Y\left[k + \frac{n}{2}\right] \leftarrow Y^0[k] - \omega_n^k Y^1[k]$  //  $A(-\omega_n^k) = A^0\left(\omega_{\frac{n}{2}}^k\right) - \omega_n^k A^1\left(\omega_{\frac{n}{2}}^k\right)$ 
11  return  $Y$ 
```

---

**Time Complexity:**  $T(n) = 2T\left(\frac{n}{2}\right) + O(n) = O(n \log n)$ .

Therefore we can evaluate a  $n-1$  degree polynomial in all the  $n^{th}$  roots of unity in  $O(n \log n)$  time. Hence with this algorithm we will get evaluations of the polynomial  $C(x) = A(x)B(x)$  in all the  $2n^{th}$  roots of unity. Now we need to interpolate the polynomial  $C(x)$  from its evaluations. We will describe the process in the next subsection.

### 3.2.3 Interpolation from Evaluations at Roots of Unity

In this section we will show how to interpolate a  $n-1$  degree polynomial from evaluations at all  $n^{th}$  roots of unity. Previously we had

$$\underbrace{\begin{bmatrix} C(\omega_n^0) \\ C(\omega_n^1) \\ C(\omega_n^2) \\ \vdots \\ C(\omega_n^{n-1}) \end{bmatrix}}_Y = \underbrace{\begin{bmatrix} 1 & \omega_n^0 & \omega_n^{0 \cdot 2} & \dots & \omega_n^{0 \cdot (n-1)} \\ 1 & \omega_n^1 & \omega_n^{1 \cdot 2} & \dots & \omega_n^{1 \cdot (n-1)} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{(n-1) \cdot 2} & \dots & \omega_n^{(n-1) \cdot (n-1)} \end{bmatrix}}_{V = \text{Vandermonde Matrix}} \underbrace{\begin{bmatrix} c_0 \\ c_1 \\ c_2 \\ \vdots \\ c_{n-1} \end{bmatrix}}_C$$

Now vandermonde matrix is invertible since all the  $n^{th}$  roots are distinct. Therefore  $C = V^{-1}Y$ . But we can not do a matrix inversion to interpolate the polynomial because that will take  $O(n^2)$  time. Instead we have this beautiful result:

**Lemma 3.2.2**

$(V^{-1})_{j,k} = \frac{1}{n} \omega_n^{-jk}$  for all  $0 \leq j, k \leq n-1$

**Proof:** Consider the matrix  $n \times n$  matrix  $T$  such that  $(T)_{j,k} = \frac{1}{n} \omega_n^{-jk}$ . Now we will show  $VT = I$ . This will confirm that  $V^{-1} = T$ . Now

$$\sum_{k=0}^{n-1} (V)_{i,j} (T)_{j,k} = \sum_{k=0}^{n-1} \omega_n^{ij} \times \frac{1}{n} \omega_n^{-jk} = \frac{1}{n} \sum_{k=0}^{n-1} (\omega_n^{i-k})^j = \begin{cases} \frac{1}{n} \sum_{k=0}^{n-1} 1 = 1 & \text{when } i = k \\ \frac{1}{n} \frac{1 - \omega_n^n}{1 - \omega} = 0 & \text{when } i \neq k \end{cases}$$

Hence in  $VT$  there are 1's on the diagonal and rest of the locations are 0. Hence  $VT = I$ . So  $V^{-1} = T$ . ■

Hence we can see the inverse of the vandermonde matrix is also a vandermonde matrix with a scaling factor. We will denote  $y_i = C(\omega_n^i)$  for  $i \in \llbracket n-1 \rrbracket$  since these values are given to us some how and we have to find the corresponding polynomial. Therefore we have

$$\underbrace{\begin{bmatrix} c_0 \\ c_1 \\ c_2 \\ \vdots \\ c_{n-1} \end{bmatrix}}_C = \frac{1}{n} \underbrace{\begin{bmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-1 \cdot 2} & \cdots & \omega_n^{-1 \cdot (n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \cdots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-(n-1) \cdot 2} & \cdots & \omega_n^{-(n-1) \cdot (n-1)} \end{bmatrix}}_{V^{-1}} \underbrace{\begin{bmatrix} y_0 \\ y_1 \\ y_2 \\ \vdots \\ y_{n-1} \end{bmatrix}}_Y$$

**Observation.**  $nc_j = y_0 + y_1 \omega_n^{-j} + y_2 \omega_n^{-2j} + \cdots + y_{n-1} \omega_n^{-(n-1)j}$  for all  $j \in \llbracket n-1 \rrbracket$ .

We can also see this situation as we have the polynomial  $Y(x) = y_0 + y_1 x + y_2 x^2 + \cdots + y_{n-1} x^{n-1}$  and  $c_j$  is just  $Y(x)$  evaluated as  $\omega_n^{-j} = \omega_n^{n-j}$  multiplied by  $n$ . Hence we just reindex the  $n^{th}$  roots of unity and evaluate  $Y$   $n^{th}$  roots of unity in  $O(n \log n)$  time using the algorithm described in [subsection 3.2.2](#)

# Dynamic Programming

## Definition 4.1: Dynamic Programming

Dynamic Programming has 3 components:

1. Optimal Substructure: Reduce problem to smaller independent problems
2. Recursion: Use recursion to solve the problems by solving smaller independent problems
3. Table Filling: Use a table to store the result to solved smaller independent problems.

## 4.1 Longest Increasing Subsequence

LONGEST INCREASING SUBSEQUENCE

**Input:** Sequence of distinct integers  $A = (a_1, \dots, a_n)$

**Question:** Given an array of distinct integers find the longest increasing subsequence i.e. return maximum size set  $S \subseteq [n]$  such that  $\forall i, j \in S, i < j \implies a_i < a_j$

### 4.1.1 $O(n^2)$ Time Algorithm

Given  $A = (a_1, \dots, a_n)$  first we will create a  $n$ -length array where  $i^{th}$  entry stores the length and longest increasing subsequence ending at  $a_i$ . Certainly we have the following recursion relation

$$LIS(k) = 1 + \max_{j < k, a_j < a_k} \{LIS(j)\}$$

since if a subsequence  $S \subseteq [n]$  is the longest increasing subsequence ending at  $a_k$  then certainly  $S - \{k\}$  is the longest increasing subsequence which ends at  $a_j < a_k$  for some  $j < k$ . Hence in the table we start with 1st position and using the recursion relation we fill the table from left. And after the table is filled we look for which entry of the table has maximum length. So the algorithm will be following:

---

#### Algorithm 10: LIS(A)

---

**Input:** Sequence of distinct integers  $A = (a_1, \dots, a_n)$

**Output:** Maximum size set  $S \subseteq [n]$  such that  $\forall i, j \in S, i < j \implies a_i < a_j$ .

```

1 begin
2   Create an array  $T$  of length  $n$ 
3   for  $i \in [n]$  do
4      $T[i][1] \leftarrow 1 + \max\{T[j][1] : j < i, a_j < a_i\}$            // Finds LIS[i]
5      $T[i][2] \leftarrow T[T[i][1] - 1][2]$ 
6    $Index \leftarrow \max\{T[j][1] : j \in [n]\}$ 
7   return  $T[Index]$ 

```

---

**Time Complexity:** For each iteration of the loop it takes  $O(n)$  time to find  $\text{LIS}[i]$ . Hence the time complexity of this algorithm is  $O(n^2)$ .

#### 4.1.2 $O(n \log n)$ Time Algorithm

In the following algorithm we update the longest increasing sequence every time we see a new element of the given sequence. At any time we keep the best available sequence.

**Idea.** We can make an increasing subsequence longer by picking the smallest number for position  $k$  so that there is an increasing subsequence of length  $k$ . Doing this we can maximize the length of the subsequence.

##### Theorem 4.1.1

Is  $S \subseteq A$  is the longest increasing subsequence of length  $t$  then for any  $k \in [t]$  the number  $S(k)$  is the smallest number in subarray of  $A$  starting at first and ending at  $S(k)$  such that there is an increasing subsequence of length  $k$  ending at  $S(k)$ .

**Proof:** Suppose  $\exists k \in [t]$  such that  $k$  is the smallest number in  $[t]$  such that  $S(k)$  is not the smallest number to satisfy the condition. Now denote the subarray of  $A$  starting at first and ending at  $S(k)$  by  $A_k$ . Now let  $x \in A_k$  be the smallest number in  $A_k$  such that there is an increasing subsequence of length  $k$  ending at  $x$ . Certainly  $x < S(k)$ . Now since  $k$  is the smallest index which does not satisfy the given condition,  $\forall j \in [k-1]$ ,  $S(j)$  is the smallest number in  $A_j$  such that there is an increasing subsequence of length  $j$  ending at  $S(j)$ . Then consider the subsequence  $\{S(1), \dots, S(k-1), x, S(k), S(k+1), \dots, S(t)\}$ . This is an increasing subsequence of  $A$  and has length  $t+1$ . But this contradicts the minimality of  $S$ . Hence contradiction. Every element of  $S$  follows the given condition. ■

So we will construct an increasing subsequence by gradually where each step this property is followed, i.e. at each step we will ensure that the sequence built at some time have the above property. So now we describe the algorithm.

---

##### Algorithm 11: QUICKLIS( $A$ )

---

**Input:** Sequence of distinct integers  $A = (a_1, \dots, a_n)$   
**Output:** Maximum size set  $S \subseteq [n]$  such that  $\forall i, j \in S, i < j \implies a_i < a_j$ .

```

1 begin
2   Create an array  $T$  of length  $n$  with all entries 0
3   Create an array  $M$  of length  $n$ 
4   for  $i = 1, \dots, n$  do
5      $M[i] \leftarrow \infty$ 
6   for  $i = 1, \dots, n$  do
7      $k \leftarrow$  Find smallest index  $i$  such that  $M[k] > a_i$  using BINARY-SEARCH
8      $M[k] \leftarrow i$ 
9      $T[i] \leftarrow M[k-1]$  // Pointer to the previous element of the sequence
10   $l \leftarrow$  Largest  $l$  such that  $M[l]$  is finite
11  Create an array  $S$  of length  $l$ 
12  for  $i = l, \dots, 1$  do
13    if  $i = l$  then
14       $S[l] \leftarrow M[l]$ 
15      Continue
16     $S[i] \leftarrow T[S[i+1]]$  //  $T[S[i+1]]$  is pointer to previous value of sequence
17  return  $(l, S)$ 
```

---

**Time Complexity:** To create the arrays and the first for loop takes  $O(n)$  time. In each iteration of the for loop at line 6 it takes  $O(\log n)$  time to find  $k$  and rest of the operations in the loop takes constant time. So the for loop takes  $O(n \log n)$  time. Then To find  $l$  and creating  $S$  it takes  $O(n)$  time. Then in the for loop at line 12 in each iteration it takes constant time. So the for loop at line 12 takes in total  $O(n)$  time. Therefore the algorithm takes  $O(n \log n)$  time.

We will do the proof of correctness of the algorithm now.

**Lemma 4.1.2**

For any index  $M[k]$  is non increasing

**Proof:** Every time we change a value of  $M[k]$  we replace by something smaller. So  $M[k]$  is non increasing. ■

We denote the state of array  $M$  at  $i^{th}$  iteration by  $M^i$ . Then we have the following lemma:

**Lemma 4.1.3**

At any time  $i$ ,  $M^i[1] \leq M^i[2] \leq \dots \leq M^i[n]$

**Proof:** We will prove this by induction on  $i$ . The base case follows naturally. Now for  $i^{th}$  iteration suppose  $M^i[k]$  is replaced by  $x_i$ . Then we know  $\forall j < k$  we have  $M^i[j] \leq x_i$ . By inductive hypothesis at time  $t-1$  we have  $M$  as an increasing sequence. Now before replacing  $M^i[k] \leq M^i[k+1] \leq \dots \leq M^i[n]$ . Now by [Lemma 4.1.2](#)  $M^i[k]$  is nonincreasing. So So we still have  $M^i[1] \leq \dots \leq M^i[k-1] \leq x_i \leq M^i[k+1] \leq \dots \leq M^i[n]$ . Hence by mathematical induction it holds. ■

Now suppose at  $i^{th}$  iteration  $k_i$  is largest such that  $M^i[k_i] < \infty$ . Then  $S^i$  denote the set constructed like the way we constructed at line 12–16 in the algorithm i.e.

$$S^i[k_i] = M^i[k_i] \quad \text{and} \quad S^i[j] = T[S^i[j+1]] \quad \forall j \in [k_i - 1]$$

**Lemma 4.1.4**

After any  $i^{th}$  iteration, for  $k \in [n]$  if  $M^i[k] < \infty$  then  $S^i[k]$  stores the smallest value in  $x_1, \dots, x_i$  such that there is an increasing subsequence of size  $k$  that ends in  $S^i[k]$ .

**Proof:** We will induction on  $i$ . Base case: This is true after first iteration since only  $M^1[1] < \infty$ . So this naturally follows.

Suppose this is true after  $i$  iterations. Now at  $(i+1)^{th}$  iteration suppose  $t$  be the smallest index such that  $M^i[t] > x_{i+1}$ . Then we have

$$M^i[1], \dots, M^i[t-1] < x_{i+1} < M^i[k], \dots, M^i[n] \implies S^i[1], \dots, S^i[t-1] < x_{i+1} < S^i[k], \dots, S^i[k_i]$$

Now for  $k \leq t-1$  it is true by the inductive hypothesis. For  $k > t$  and if  $M^{i+1}[k] < \infty$  then  $S^{i+1}[k]$  is the smallest value in  $x_1, \dots, x_{i+1}$  such that there is an increasing subsequence of size  $k$  that ends in  $S^{i+1}[k]$  since this was true for  $i^{th}$  iteration.

Now only the case when  $k = t$  is remaining. If  $S^{i+1}[k]$  is not the smallest value in  $x_1, \dots, x_{i+1}$  to have an increasing subsequence of size  $k$  ending at  $S^{i+1}[k]$  then let  $x_j$  was the smallest value to satisfy this condition where  $j < i+1$ . Then naturally  $x_j < x_{i+1}$ . Then  $M^i[t] \leq x_j < x_{i+1}$ . But we  $t$  was the smallest number such that  $M^i[t] > x_{i+1}$ . Hence contradiction. Therefore  $S^i[k]$  is the smallest value in  $x_1, \dots, x_{i+1}$  to have an increasing subsequence of size  $k$  ending at  $S^{i+1}[k]$ .

Therefore by mathematical induction this is true for all iterations. ■

**Theorem 4.1.5**

$S$  is the longest increasing subsequence of  $A$ .

**Proof:** After the  $n^{th}$  iteration  $S^n = S$  and  $k_n = l$ . Hence by [Lemma 4.1.4](#) we can say for all  $k \in [l]$ ,  $S[k]$  is the smallest number such that there is an increasing sequence of length  $k$  ending at  $S[k]$ . Now we want to show that this increasing sequence is the longest increasing subsequence of  $A$ . Suppose  $S$  is not the longest increasing subsequence. Let  $T$  be the longest increasing subsequence of length  $t$ . Then suppose  $j \leq l$  be the smallest index such that  $S[j] \neq T[j]$ . Now  $S[j]$  is the smallest number in  $x_1, \dots, x_n$  such that there is an increasing subsequence of length  $j$  ending at  $S[j]$ . Hence we have  $S[j] < T[j]$ . Now for all  $i < j$  we have  $S[i] = T[i]$ . Then we form this new subsequence  $\hat{T} = \{T[1], T[2], \dots, T[j-1], S[j], T[j], \dots, T[t]\}$ . Certainly  $\hat{T}$  has length  $t+1$  and it is also an increasing subsequence. But this contradicts the maximality condition of  $T$ . Hence  $S$  is indeed the longest increasing subsequence. ■

## 4.2 Optimal Binary Search Tree

OPTIMAL BST

**Input:** A sorted array  $A = (a_1, \dots, a_n)$  of search keys and an array of their probability distributions  $P = (p(a_1), \dots, p(a_n))$

**Question:** Given array of keys  $A$  and their probabilities the probability of accessing  $a_i$  is  $p(a_i)$  then return a binary tree with the minimum cost where for any binary tree  $T$ ,  $\text{Cost}(T) = \sum_{i=1}^n p(a_i) \cdot \text{height}_T(a_i)$ .

So let  $T$  be the optimal binary search tree with  $a_k$  as its root for some  $k \in [n]$ . Let  $T_l$  and  $T_r$  denote the tree rooted at the left child and right child of  $a_k$  in  $T$  respectively. Then:

$$\text{Cost}(T) = p_k + \sum_{i < k} p_i (1 + \text{height}_{T_l}(a_i)) + \sum_{i > k} p_i (1 + \text{height}_{T_r}(a_i)) = \sum_{i=1}^n p_i + \underbrace{\sum_{i < k} p_i \cdot \text{height}_{T_l}(a_i)}_{\text{Cost}(T_l)} + \underbrace{\sum_{i > k} p_i \cdot \text{height}_{T_r}(a_i)}_{\text{Cost}(T_r)}$$

We will use the use of notion in general  $\text{OPTCost}(i, k) = \text{Cost}(T_i^k)$  where  $T_i^k$  is the optimal binary tree of the subarray  $A[i \dots k]$  for any  $i \leq k \leq n$ . Therefore we arrive at the following recurrence relation

$$\text{OPTCost}(i, k) = \begin{cases} 0 & \text{when } i > k \\ \sum_{j=i}^k p(a_j) + \min_{i \leq r \leq k} \{ \text{OPTCost}(i, r-1) + \text{OPTCost}(r+1, k) \} & \text{otherwise} \end{cases}$$

So the algorithm for constructing the optimal binary search tree is following:

---

**Algorithm 12:** OPTIMALBST( $A, P$ )

---

**Input:** A sorted array  $A = (a_1, \dots, a_n)$  of search keys and an array of their probability distributions  $P = (p(a_1), \dots, p(a_n))$

**Output:** Binary Tree  $T$  with the minimum search cost,  $\text{Cost}(T) = \sum_{i=1}^n p(a_i) \cdot \text{height}_T(a_i)$

---

```

1 begin
2   for  $i = 1, \dots, n$  do
3      $\text{OPTCost}[i, i] \leftarrow (p(a_i), a_i)$ ,  $\text{OPTCost}[0, i] \leftarrow (0, \text{None})$ 
4   for  $d = 2, \dots, n$  do
5     for  $i \in [n+1-d]$  do
6        $\text{minval} \leftarrow 0$ 
7       for  $k = i+1, \dots, i+d-2$  do
8          $\text{newval} \leftarrow \text{OPTCost}[i, k-1][1] + \text{OPTCost}[k+1, i+d-1][1]$ 
9         if  $\text{minval} > \text{newval}$  then
10            $\text{minval} \leftarrow \text{newval}$ 
11            $\text{Index} \leftarrow k$ 
12        $\text{OPTCost}[i, i+d-1] \leftarrow \left( \text{minval} + \sum_{k=1}^{i+d-1} p(a_k), k \right)$ 
13        $a_k.\text{left} \leftarrow \text{OPTCost}[i, k-1][2]$ 
14        $a_k.\text{right} \leftarrow \text{OPTCost}[k+1, i+d-1][2]$ 
15   return  $\text{OPTCost}[1, n]$ 

```

---

**Time Complexity:** To two for loops at line 4 and line 5 takes  $O(n^2)$  many iterations. Now the inner most for loop at line 7 runs  $O(n)$  iterations where in each iterations it takes constant runtime. So the total running time of the algorithm is  $O(n^3)$ .

# Greedy Algorithm

## 5.1 Maximal Matching

MAXIMAL MATCHING

**Input:** Graph  $G = (V, E)$

**Question:** Find a maximal matching  $M \subseteq E$  of  $G$

Before diving into the algorithm to find a matching or maximal matching we first define what is a matching.

### Definition 5.1.1: Matching

Given a graph  $G = (V, E)$ ,  $M \subseteq E$  is said to be a matching if  $M$  is an independent set of edges i.e. no two edges of  $M$  are incident on same vertex.

### Definition 5.1.2: Maximal Matching

For a graph  $G = (V, E)$  a matching  $M \subseteq E$  is maximal if it cannot be extended and still by adding an edge.

There is also a maximum matching which can be easily understood from the name:

### Definition 5.1.3: Maximum Matching

For a graph  $G = (V, E)$  a matching  $M \subseteq E$  is maximum if it is maximal and has the maximum size among all the maximal matchings.

**Idea.** The idea is to create a maximal matching we will just go over each edge one by one and check if after adding them to the set  $M$  the matching property still holds.

---

### Algorithm 13: MAXIMAL-MATCHING

---

**Input:** Graph  $G = (V, E)$

**Output:** Maximal Matching  $M \subseteq E$  of  $G$

```

1 begin
2    $M \leftarrow \emptyset$ 
3   Order the edges  $E = \{e_1, \dots, e_k\}$  arbitrarily
4   for  $e \in E$  do
5     if  $M \cup \{e\}$  is matching then
6        $M \leftarrow M \cup \{e\}$ 
7   return  $M$ 
```

---

**Question 5.1**

Do we always get the largest possible matching?

**Solution:** Clearly algorithm output is not optimal always. We get a maximal matching sure. But we don't get a maximum matching always. For example the following graph

If we start from  $e_1$  we get the matching  $\{e_1, e_2\}$  which is maximum matching but if we start from  $e_3$  then we get only the maximal matching  $\{e_3\}$  which is not maximum. ■

Since the algorithm output may not be optimal always we can ask the following question

**Question 5.2**

How large is the matching obtained compared to the maximum matching?

This brings us to the following result:

**Theorem 5.1.1**

For any graph  $G$  let the greedy algorithm obtains the matching  $M$  and the maximum matching is  $M^*$ . Then

$$|M| \geq \frac{1}{2}|M^*|$$

**Proof:** Consider an edge  $e \in M^*$  but  $e \notin M$ . Since  $e$  wasn't picked in  $M$ ,  $\exists e' \in M \setminus M^*$  such that  $e$  and  $e'$  are incident on same vertex. Thus define the function  $f: M^* \rightarrow M$  where

$$f(e) = \begin{cases} e & \text{when } e \in M \\ e' & \text{when } e \in M^* \setminus M \text{ where } e' \in M \setminus M^* \text{ such that } e' \cap e \neq \emptyset \end{cases}$$

Now note that there are at most two edges in  $M^*$  that are adjacent to an edge  $e' \in M$  which will be mapped to  $e'$ . Hence

$$|M \setminus M^*| \geq \frac{1}{2}|M^* \setminus M|$$

Therefore  $|f^{-1}(e')| \leq 2 \forall e' \in M$ . Hence

$$|M^*| = |M \cap M^*| + |M^* \setminus M| \leq |M \cap M^*| + 2|M \setminus M^*| \leq 2|M|$$

Therefore we have the result  $|M| \geq \frac{1}{2}|M^*|$ . ■

**Alternate Proof:** Let  $M_1$  and  $M_2$  are two matchings. Consider the symmetric difference  $M_1 \Delta M_2$ . This consists of edges that are in exactly one of  $M_1$  and  $M_2$ . Now in  $M \Delta M^*$  we have the following properties:

- (a) Every vertex in  $M \Delta M^*$  has degree  $\leq 2 \implies$  Each component is a path or an even cycle.
- (b) The edges of  $M$  and  $M^*$  alternate.

Now we will prove the following property about the connected components of  $M \Delta M^*$ .

**Claim:** No connected component is a single edge.

**Proof:** This is because let  $e$  be a connected component. So the two edges  $e_1, e_2$  which are adjacent to  $e$ , they are either in both  $M$  and  $M^*$  or not in  $M$  and  $M^*$ . The former case is not possible because then  $e_1, e_2, e$  are all in either  $M$  or  $M^*$  which is not possible as they do not satisfy the condition of matching. For the later case since  $M^*$  is maximal matching,  $e \in M^*$ . Then  $e \notin M$ . That means  $e, e_1, e_2 \notin M$  which is not possible since  $M$  is also a maximal matching. Therefore no connected component is a single edge. ■

Therefore every path has length  $\geq 2$ . Therefore ratio of # edges of  $M$  to # edges of  $M^*$  in a path is  $\leq 2$ . And for cycles we have # edges of  $M$  = # edges of  $M^*$ . So in every connected component  $C$  of  $M \Delta M^*$  the ratio  $\frac{|M^* \cap C|}{|M \cap C|} \leq 2$ . Therefore we have

$$\frac{|M^*|}{|M|} = \frac{|M \cap M^*| + \sum_C |M^* \cap C|}{|M \cap M^*| + \sum_C |M \cap C|} \leq 2$$

Hence we have  $|M| \geq \frac{1}{2}|M^*|$ . ■

## 5.2 Huffman Encoding

### HUFFMAN CODING

**Input:**  $n$  symbols  $A = (a_1, \dots, a_n)$  and their frequencies  $P = (f_1, \dots, f_n)$  of using symbols

**Question:** Create a binary encoding such that:

- Prefix Free: The code for one word can not be prefix for another code
- Minimality: Minimize  $\text{COST}(b) = \sum_{i=1}^n f_i \cdot \text{LEN}(b(a_i))$  where  $b : A \rightarrow \{0, 1\}^*$  is the binary encoding

Assignment of binary strings can also be seen as placing the symbols in a binary tree where at any node 0 means left child and 1 means right child. Then the first condition implies that there can not be two codes which lie in the same path from the root to a leaf. I.e. it means that all the codes have to be in the leaves. Then the length of the binary coding for a symbol is the height of the symbol in the binary tree.

We can think the frequencies as the probability of appearing for a letter. We denote the probability of appearing of the letter  $a_i$  by  $p(a_i) := \frac{f_i}{\sum_{i=1}^n f_i}$ . So then we can see the updated cost function

$$\text{COST}(b) = \sum_{i=1}^n p(a_i) \cdot \text{LEN}(b(a_i))$$

And from now on we will see the frequencies as probabilities and cost function like this

### 5.2.1 Optimal Binary Encoding Tree Properties

Then our goal is to find a binary tree with minimum cost where all the symbols are at the leaves. We have the following which establish the optimality of Huffman encoding over all prefix encodings where each symbol is assigned a unique string of bits.

#### Lemma 5.2.1

In the optimal encoding tree least frequent element has maximum height.

**Proof:** Suppose that is not the case. Let  $T$  be the optimal encoding tree and let the least frequent element  $x$  is at height  $h_1$  and the element with the maximum height is  $y$  with height  $h_2$  and we have  $h_1 < h_2$ . Then we construct a new encoding tree  $T'$  where we swap the positions of  $x$  and  $y$ . So in  $T'$  height of  $y$  is  $h_1$  and height of  $x$  is  $h_2$ . Then

$$\text{COST}(T) - \text{COST}(T') = (p(x)h_1 + p(y)h_2) - (p(x)h_2 + p(y)h_1) = (p(x) - p(y))(h_1 - h_2)$$

Since  $p(x) < p(y)$  and  $h_1 < h_2$  we have  $\text{COST}(T) - \text{COST}(T') > 0$ . But that is not possible since  $T$  is the optimal encoding tree. So  $T$  should have the minimum cost. Hence contradiction.  $x$  has the maximum height. ■

**Lemma 5.2.2**

The optimal encoding binary tree must be complete binary tree. (i.e. every non-leaf node has exactly 2 children)

**Proof:** Suppose  $T$  be the optimal binary tree and there is a non-leaf node  $r$  which has only one child at height  $h$ . By Lemma 5.2.1 the least frequent element  $x$  has the maximum height,  $h_m$ .

Then consider the new tree  $\hat{T}$  where we place the least frequent element at height  $h$  and make it the second child of the node  $r$ . Then

$$\text{Cost}(T) - \text{Cost}(\hat{T}) = p(x)h_m - p(x)h = p(x)(h_m - h) > 0$$

But this is not possible as  $T$  is the optimal binary tree and it has the minimal cost. Hence contradiction. Therefore the optimal encoding binary tree must be a complete binary tree. ■

**Lemma 5.2.3**

There is an optimal binary encoding tree such that the least frequent element and the second least frequent element are siblings at the maximum height.

**Proof:** Let  $T$  be optimal binary encoding tree. Suppose  $x, y$  are the least frequent element and the second least frequent element. And suppose  $b, c$  be two siblings at the maximum height of the tree (There may be many such siblings, and if so pick any such pair.). If  $\{x, y\} = \{b, c\}$  we are done. So suppose not. Let the frequencies of  $x, y, b, c$  are respectively  $p(x), p(y), p(b), p(c)$  and heights of  $x, y, b$  are  $h_x, h_y$  and  $h$  respectively. WLOG assume  $p(x) \leq p(y)$  and  $p(b) \leq p(c)$ .

Now since we know  $x, y$  have the smallest frequencies we have  $p(x) \leq p(b)$  and  $p(y) \leq p(c)$ . And since  $b, c$  have the maximum height we have  $h_x, h_y \geq h$ . So we switch the position of  $x$  with  $b$  to form the new tree  $T'$ . And from  $T'$  we swap the positions for  $y$  and  $c$  to form a new tree  $T''$ .

Figure 5.1: Showing that the lowest probability nodes are siblings at the tree's lowest level.

Now we will calculate how the cost changes as we go from  $T$  to  $T'$  and  $T'$  to  $T''$ . First check for  $T \rightarrow T'$ . Almost all the nodes contribute the same except  $x, b$ . So we have

$$\text{Cost}(T) - \text{Cost}(T') = (h_x \cdot p(x) + h \cdot p(b)) - (h_x \cdot p(b) + h \cdot p(x)) = (p(b) - p(x))(h - h_x) \geq 0$$

Therefore swapping  $x$  and  $b$  does not increase the cost and since  $T$  is the optimal binary encoding tree the cost doesn't decrease either. Therefore the costs are equal. Hence  $T'$  is also an optimal tree.

Similarly we calculate cost for going from  $T'$  to  $T''$  we have

$$\text{Cost}(T') - \text{Cost}(T'') = (h_y \cdot p(y) + h \cdot p(c)) - (h_y \cdot p(c) + h \cdot p(y)) = (p(c) - p(y))(h - h_y) \geq 0$$

Therefore swapping  $y$  and  $c$  also does not increase the cost and since  $T'$  is the optimal binary encoding tree the cost doesn't decrease either. Therefore the costs are equal. Hence  $T''$  is also an optimal tree. Hence  $T''$  is the optimal tree where the least frequent element and second last frequent element are siblings. ■

By the Lemma 5.2.2 and Lemma 5.2.3 we have that the least frequent element and the second least frequent element are siblings and they have the maximum height.

**Observation.** The cost of the trees  $T_n$  and  $T_{n-1}$  differ only by the fixed term  $p(z) = p(x) + p(y)$  which does not depend on the tree's structure. Therefore minimizing the cost for  $T_n$  is equivalent to minimizing the cost of  $T_{n-1}$ .

**Theorem 5.2.4**

Given an instance with symbols  $\mathcal{I}$ :

$$\begin{array}{cccccccc} a_1, & a_2, & \cdots, & a_i, & \cdots, & a_j, & \cdots, & a_n \\ p(a_1), & p(a_2), & \cdots, & p(a_i), & \cdots, & p(a_j), & \cdots, & p(a_n) \end{array} \quad \text{with probabilities}$$

such that  $a_i, a_j$  are the least frequent and second least frequent elements respectively. Consider the instance with  $n - 1$  symbols  $\mathcal{I}'$ :

$$\begin{array}{cccccccccccc} a_1, & a_2, & \cdots, & a_{i-1}, & a_{i+1}, & \cdots, & a_{j-1}, & a_{j+1}, & \cdots, & a_n, & z \\ p(a_1), & p(a_2), & \cdots, & p(a_{i-1}), & p(a_{i+1}), & \cdots, & p(a_{j-1}), & p(a_{j+1}), & \cdots, & p(a_n), & p(a_i) + p(a_j) \end{array}$$

Let  $T'$  be the optimal tree for this instance  $\mathcal{I}'$ . Then there is an optimal tree for the original instance  $\mathcal{I}$  obtained from  $T'$  by replacing the leaf of  $b$  by an internal node with children  $a_i$  and  $a_j$ .

**Proof:** We will prove this by contradiction. Suppose  $\hat{T}$  is optimal for  $\mathcal{I}$ . Then  $\text{Cost}(\hat{T}) < \text{Cost}(T)$ . In  $\hat{T}$  we know  $a_i$  and  $a_j$  are siblings by Lemma 5.2.3. Now consider  $\hat{T}'$  for instance  $\mathcal{I}'$  where we merge  $a_i, a_j$  leaves and their parent into a leaf for symbol  $z$ .

Then

$$\text{Cost}(\hat{T}') = \text{Cost}(\hat{T}) - p(a_i) - p(a_j) < \text{Cost}(T) - p(a_i) - p(a_j) = \text{Cost}(T')$$

This contradicts the fact that  $T'$  is optimal binary encoding tree for  $\mathcal{I}'$ . Hence  $T$  is optimal. ■

## 5.2.2 Algorithm

**Idea:** We are going to build the tree from the leaf level. We will take two characters  $x, y$ , and “merge” them into a single character,  $z$ , which then replaces  $x$  and  $y$  in the alphabet. The character  $z$  will have probability equal to the sum of  $x$  and  $y$ ’s probabilities. Then we continue recursively building the code on the new alphabet, which has one fewer character.

Since we always need the least frequent element and the second least frequent element we have to use the data structure called MIN-PRIORITY QUEUE. So the following algorithm uses a MIN-PRIORITY QUEUE  $Q$  keyed on the probabilities to identify the two least frequent objects.

**Time Complexity:** To create the priority queue it takes  $O(n)$  time in line 4-5. Then for each iteration of the for loop in line 6 the EXTRACT-MIN operation takes  $O(\log n)$  time and then to insert an element it also takes  $O(\log n)$  time. Hence each iteration takes  $O(\log n)$  time. Since the for loop has  $n - 1 = O(n)$  many iterations the running time for the algorithm is  $O(n \log n)$ .

**Remark:** We can reduce the running time to  $O(n \log \log n)$  by replacing the binary min-heap with a van Emde Boas tree.

**Algorithm 14:** HUFFMAN-ENCODING( $A, P$ )

---

**Input:** Set of  $n$  symbols  $A = \{a_1, \dots, a_n\}$  and their probabilities  $P = \{p_1, \dots, p_n\}$

**Output:** Optimal Binary Encoding  $b : A \rightarrow \{0, 1\}^*$  for  $A$  with minimum  $\text{COST}(b) = \sum_{i=1}^n p(a_i) \cdot \text{LEN}(b(a_i))$ .

---

```

1 begin
2    $n \leftarrow |A|$ 
3    $Q \leftarrow \text{MIN-PRIORITY QUEUE}$ 
4   for  $x \in A$  do
5      $\text{INSERT}(Q, x)$ 
6   for  $i = 1, \dots, n - 1$  do
7      $z \leftarrow \text{New internal tree node}$ 
8      $x \leftarrow \text{EXTRACT-MIN}(Q), y \leftarrow \text{EXTRACT-MIN}(Q)$ 
9      $\text{left}[z] \leftarrow x, \text{right}[z] \leftarrow y$ 
10     $p(z) \leftarrow p(x) + p(y)$ 
11     $\text{INSERT}(Q, z)$ 
12  return Last element left in  $Q$  as root

```

---

**Theorem 5.2.5** Correctness of Huffman's Algorithm

The above Huffman's algorithm produces an optimal prefix code tree

**Proof:** We will prove this by induction on  $n$ , the number of symbols. For base case  $n = 1$ . There is only one tree possible. For  $n = k$  we know that by [Lemma 5.2.3](#) and [Lemma 5.2.1](#) that the two symbols  $x$  and  $y$  of lowest probabilities are siblings and they have the maximum height. Huffman's algorithm replaces these nodes by a character  $z$  whose probability is the sum of their probabilities. Now we have 1 less symbols. So by inductive hypothesis Huffman's algorithm computes the optimal binary encoding tree for the  $k - 1$  symbols. Call it  $T_{n-1}$ . Then the algorithm replaces  $z$  with a parent node with children  $x$  and  $y$  which results in a tree  $T_n$  whose cost is higher by a fixed amount  $p(z) = p(x) + p(y)$ . Now since  $T_{n-1}$  is optimal by [Theorem 5.2.4](#) we have  $T_n$  is also optimal. ■

## 5.3 Matroids

**Definition 5.3.1: Matroid**

A matroid  $M = (E, \mathcal{I})$  has a ground set  $E$  and a collection  $\mathcal{I}$  of subsets of  $E$  called the *Independent Sets* st

1. Downward Closure: If  $Y \in \mathcal{I}$  then  $\forall X \subseteq Y, X \in \mathcal{I}$ .
2. Exchange Property: If  $X, Y \in \mathcal{I}, |X| < |Y|$  then  $\exists e \in Y - X$  such that  $X \cup \{e\}$  also written as  $X + e \in \mathcal{I}$

An element  $x \in E$  extends  $A \in \mathcal{I}$  if  $A \cup \{x\} \in \mathcal{I}$ . And  $A$  is maximal if no element can extend  $A$ .

**Lemma 5.3.1**

If  $A, B$  are maximal independent set, then  $|A| = |B|$  i.e. all maximal independent sets are also maximum

**Proof:** Suppose  $|A| \neq |B|$ . WLOG assume  $|A| > |B|$ . Then by the exchange property  $\exists e \in A - B$  such that  $B \cup \{e\} \in \mathcal{I}$ . But we assumed that  $B$  is maximal independent set. Hence contradiction. We have  $|A| = |B|$ . ■

**Base:** Maximal Independent sets are called bases.

**Rank of  $S \in \mathcal{I}$ :**  $\max\{|X| : X \subseteq S, X \in \mathcal{I}\}$

**Rank of a Matroid:** Size of the base.

**Span of  $S \in \mathcal{I}$ :**  $\{e \in E : \text{rank}(S) = \text{rank}(S + e)\}$

### 5.3.1 Examples of Matroid

- **Uniform Matroid:** Given  $E = \{e_1, \dots, e_n\}$ , and  $k \in \mathbb{Z}_0$  take  $\mathcal{I} = \{S \subseteq E: |S| \leq k\}$

**Lemma 5.3.2**

$M = (E, \mathcal{I})$  defined as above is a matroid

**Proof:**

- ① Downward Closure:  $A \in \mathcal{I}, B \subseteq A \implies |B| \leq k \implies B \in \mathcal{I}$
- ② Exchange Property:  $A, B \in \mathcal{I}, |B| < |A| \leq k \implies |B| < k \implies \forall e \in A - B, |B \cup \{e\}| \leq k \implies B \cup \{e\} \in \mathcal{I}$

Therefore  $M$  is a matroid ■

- **Partition Matroid:** Given  $E, \{P_1, \dots, P_l\}$  such that  $E = \bigcup_{i=1}^l P_i$  and  $k_1, \dots, k_l \in \mathbb{Z}_0$  then take

$$\mathcal{I} = \{S \subseteq E: \forall k \in [l], |S \cap P_j| \leq k_j\}$$

**Lemma 5.3.3**

$M = (E, \mathcal{I})$  defined as above is a matroid

**Proof:**

- ① Downward Closure:  $A \in \mathcal{I}, B \subseteq A \implies \forall j \in [l] |B \cap P_j| \leq |A \cap P_j| \leq k_j \implies B \in \mathcal{I}$
- ② Exchange Property:  $A, B \in \mathcal{I}, |B| < |A| \implies \exists j \in [l], |B \cap P_j| < |A \cap P_j| \leq k_j \implies e \in (A \cap P_j) - (B \cap P_j), |(B \cup \{e\}) \cap P_j| = |B \cap P_j| + 1 \leq k_j \implies B \cup \{e\} \in \mathcal{I}$

Therefore  $M$  is a matroid ■

- **Laminar Matroid:** Given  $E, \mathcal{L} = \{L_1, \dots, L_l\}$  such that  $\forall i, j \in [l]$ , either  $L_i \subseteq L_j$  or  $L_i \supseteq L_j$  or  $L_i \cap L_j = \emptyset$  and also given  $k_1, \dots, k_l \in \mathbb{Z}_0$ . Then take

$$\mathcal{I} = \{S \subseteq E: \forall j \in [l], |S \cap L_j| \leq k_j\}$$

For any  $L \in \mathcal{L}$  we denote  $k(L)$  be the given number corresponding to  $L$ .

**Lemma 5.3.4**

$M = (E, \mathcal{I})$  defined as above is a matroid

**Proof:**

- ① Downward Closure:  $A \in \mathcal{I}, B \subseteq A \implies \forall j \in [l] |B \cap L_j| \leq |A \cap L_j| \leq k_j \implies B \in \mathcal{I}$
- ② Exchange Property: Let  $A, B \in \mathcal{I}$  with  $|B| < |A|$ . If there exists  $e \in A \setminus B$  such that  $e \notin L$  for any  $L \in \mathcal{L}$ , then  $|(B + e) \cap L| = |B \cap L| \leq k(L)$  for any  $L \in \mathcal{L}$ .

Hence assume that for each  $e \in A \setminus B$  there exists  $L \in \mathcal{L}$  with  $e \in L$ . For each  $e \in A \setminus B$ , let  $\mathcal{L}_e$  be the collection of  $L \in \mathcal{L}$  with  $e \in L$ . For each  $e \in A \setminus B$  and any  $L \in \mathcal{L} \setminus \mathcal{L}_e$ , we have  $|(B + e) \cap L| = |B \cap L| \leq k(L)$ .

Hence it remains to show that there exists  $e \in A \setminus B$  such that  $|(B + e) \cap L| \leq k(L)$  for any  $L \in \mathcal{L}_e$ . Note that  $\mathcal{L}_e$  is a chain, as  $\mathcal{L}$  is a laminar. Let  $\mathcal{L}' = \{L_{e_1}, \dots, L_{e_l}\}$  be the collection of inclusion-wise maximal sets in  $\mathcal{L}$  such that  $|B \cap L_{e_i}| \leq k(L_{e_i})$  with  $e_i \in A \setminus B$ . Then  $L_{e_i} \cap L_{e_j} = \emptyset$ . Moreover,  $|A| > |B|$  and  $|A \cap L_{e_i}| \leq k(L_{e_i})$  imply that  $|A \setminus (\cup L_{e_i})| > |B \setminus (\cup L_{e_i})|$ . Hence there  $\exists e_i$  such that  $|A \cap L_{e_i}| > |B \cap L_{e_i}|$ .

Now we take a look at the chain  $\mathcal{L}_{e_i}$ . For brevity we will use  $e$  instead of  $e_i$ . So in the chain  $\mathcal{L}_e = \{L_1, \dots, L_n\}$  such that we have

$$L_n \supseteq L_{n-1} \supseteq \dots \supseteq L_2 \supseteq L_1$$

Then take  $i \in [n]$  to be the largest index such that  $|A \cap L_i| \leq |B \cap L_i|$ . There will be such index because otherwise we will have  $|A| \leq |B|$  which is not possible. Then take  $e^* \in (A \cap L_{i+1}) - (L_i \cup B)$ . Such an  $e^*$  will exist because  $|A \cap L_{i+1}| > |A \cap L_i| \implies A \cap (L_{i+1} - L_i) \neq \emptyset$  and also  $A \cap (L_{i+1} - L_i) \not\subseteq B \cap (L_{i+1} - L_i)$  because otherwise we will have

$$|A \cap L_{i+1}| = |A \cap (L_{i+1} - L_i)| + |A \cap L_i| \leq |B \cap (L_{i+1} - L_i)| + |B \cap L_i| = |B \cap L_{i+1}|$$

which is not possible. Hence there exists  $e^*$  such that  $e^* \in (A \cap L_{i+1}) - (L_i \cup B)$ . Therefore take  $B^* = B \cup \{e^*\}$ . Then for all  $j < i$  we have  $B^* \cap L_j = B \cap L_j$  so we don't have a problem there. Now for all  $j \geq i$  we have  $|A \cap L_j| > |B \cap L_j|$ . Hence now  $|B^* \cap L_j| \leq |B \cap L_j| + 1 \leq |A \cap L_j| \leq k(L_j)$ . Therefore we have  $B^* \in \mathcal{I}$ . Hence the exchange property follows.

Therefore  $M$  is a matroid. ■

- **Graphic Matroid:** Given a graph  $G = (V, E)$   $E$  is the ground set and take

$$\mathcal{I} = \{E' \subseteq E : E' \text{ is acyclic}\}$$

#### Lemma 5.3.5

$M = (E, \mathcal{I})$  defined as above is a matroid

**Proof:**

- ① Downward Closure: If a set of edges  $S$  is acyclic then naturally any subset of edges of  $S$  is also acyclic. Hence downward closure property follows.
- ② Exchange Property:  $A, B \in \mathcal{I}$ , and  $|B| < |A|$ . Let  $G_1, \dots, G_k$  are the connected components due to  $B$ . For each component  $G_i$ , we have  $|G_i \cap A| \leq |G_i \cap B|$  since each component is a tree and  $B$  has maximum number of edges for that component. Then  $A$  contains an edge  $e$  connecting 2 components  $G_i$  and  $G_j$ . Then  $B \cup \{e\} \in \mathcal{I}$ .

Therefore  $M$  is a matroid ■

- **Linear Matroid:** Given a  $m \times n$  matrix  $M \in \mathbb{Z}^{m \times n}$ ,  $E = [n]$  and take

$$\mathcal{I} = \{S \subseteq E : \text{Columns of } M \text{ corresponding to } S \text{ are linearly independent}\}$$

#### Lemma 5.3.6

$M = (E, \mathcal{I})$  defined as above is a matroid

**Proof:**

- ① Downward Closure:  $A \in \mathcal{I}$ ,  $B \subseteq A$ . Subset of linearly independent set is also linearly independent. Hence  $B \in \mathcal{I}$ .
- ② Exchange Property:  $A, B \in \mathcal{I}$ ,  $|B| < |A|$ . Then take  $\text{span} \langle A \rangle$  over  $\mathbb{Q}$ . Now we know a set of integral vectors are linearly independent over integers if and only if they are linearly independent over rationals. Hence  $|A| = \dim_{\mathbb{Q}} \langle A \rangle > \dim_{\mathbb{Q}} \langle B \rangle = |B|$ . Hence we can extend  $B$  by an element  $e \in A - B$  such that  $\langle B \cup \{e\} \rangle = |B| + 1$ . Hence  $B \cup \{e\} \in \mathcal{I}$ .

Therefore  $M$  is a matroid ■

This matroid is also called Metric Matroid.

### 5.3.2 Finding Max Weight Base

MAX WEIGHT BASE

**Input:** A matroid  $M = (E, I)$  is given as an input as an oracle and a weight function  $W : E \rightarrow \mathbb{R}$ .

**Question:** Find the maximum weight base of the matroid.

We will solve this using greedy algorithm.

---

**Algorithm 15:** MAX-WEIGHT-BASE( $E, W$ )

---

**Input:** A matroid  $M = (E, I)$  is given as an input as an oracle and a weight function  $W : E \rightarrow \mathbb{R}$ .

**Output:** Find the maximum weight base of the matroid

```

1 begin
2   Assume  $w(1) \geq \dots \geq w(n)$ 
3    $S \leftarrow \emptyset$ 
4    $I \leftarrow \{S\}$ 
5   for  $i = 1$  to  $n$  do
6     if  $S + i \in I$  then
7        $S \leftarrow S + i$ 
8   return  $S$ 
```

---

#### Theorem 5.3.7

The above algorithm outputs a maximum weight base

**Proof:** Let  $M$  be a matroid. We will prove that this greedy algorithm works by inducting on  $i$ . At any iteration  $i$  we need to prove the following claim:

#### Claim 5.3.1

At any iteration  $i$  there is a max weight base  $B_i$  such that  $S_i \subseteq B_i$  and  $B_i \setminus S_i \subseteq \{i+1, \dots, n\}$ .

**Proof:** Base case:  $S = \emptyset$ . So for base case the statement is true trivially. Assume that the statement is true up to  $(i-1)$  iterations.

Now  $S_{i-1} \subseteq B_{i-1}$  where  $B_{i-1}$  is a maximum weight base and  $B_{i-1} - S_{i-1} \subseteq \{i, \dots, n\}$ . Now three cases arise:

**Case 1:** If  $i \in B_{i-1}$  then  $S_{i-1} + i \subseteq B_{i-1}$ . Therefore  $S_{i-1} + i$  is independent. So now  $B_i = B_{i-1}$  and  $S_i = S_{i-1} + i$  and  $B_i - S_i \subseteq \{i+1, \dots, n\}$ .

**Case 2:** If  $i \notin B_{i-1}$  and  $S_{i-1} + i \notin \mathcal{I}$ . Then  $S_i = S_{i-1}$  and  $B_i = B_{i-1}$ . And  $B_i - S_i \subseteq \{i+1, \dots, n\}$ .

**Case 3:** If  $i \notin B_{i-1}$  but  $S_{i-1} + i \in \mathcal{I}$ . Then  $S_i = S_{i-1} + i$ . Now  $S_i$  can be extended to a  $B'$  by adding all but one element of  $B_{i-1}$ . So  $|B'| = |B_{i-1}|$ . Let the element which is not added is  $j \in B_{i-1}$ . So  $B' = B_{i-1} + i - j$ .

$$wt(B') = wt(B_{i-1}) - wt(j) + wt(i)$$

But we have  $wt(i) \geq wt(j)$ . So  $wt(B') \geq wt(B_{i-1})$ . Now since  $B_{i-1}$  has maximum weight we have  $wt(B') = wt(B_{i-1})$ . Then our  $B_i = B'$ . So  $B_i - S_i \subseteq \{i+1, \dots, n\}$ .

Hence the claim is true for the  $i$ th stage as well. Therefore the claim is true. ■

#### Claim 5.3.2

At any iteration,  $T_i = \{t_1, \dots, t_k\}$ , then  $T_i$  is a maximum weight independent set with at most  $i$  elements

**Proof:** We will prove by induction. Base Case:  $i = 0$ . Then  $T_i = \emptyset$ . So the statement follows naturally. Assume  $T_{i-1}$  is maximum weight independent set with at most  $i-1$  elements. Now for a contradiction, say  $\hat{T}_i \in \mathcal{I}$  of size at most  $i$  with strictly larger weight than  $T_i$ . Then  $\exists x \in \hat{T}_i - T_{i-1}$  such that  $T_{i-1} \cup \{x\} \in \mathcal{I}$ . Then we have

$$wt(\hat{T}_i - x) \leq wt(T_{i-1})$$

by inductive hypothesis. The only element that extend  $T_{i-1}$  are those  $t_{i-1}$ . Therefore  $wt(x) \leq wt(t_i)$ . Hence we have

$$wt(\hat{T}_i - x) + wt(x) \leq wt(T_{i-1}) + wt(t_i) \implies wt(\hat{T}_i) \leq wt(T_i)$$

But we assumed  $wt(\hat{T}_i) > wt(T_i)$ . Hence contradiction. ■

Therefore using the claims, after the algorithm finished we have no elements left to check, so the current set has the maximum weight which is also an independent set. So the algorithm successfully returns a maximum weight base. ■

### 5.3.3 Job Selection with Penalties

FIND FEASIBLE SCHEDULE

**Input:** Set  $J$  of  $n$  jobs with deadlines  $d_1, \dots, d_n$  and rewards  $w_1, \dots, w_n$

**Question:** Each jobs unit time and we have a single machine to process their jobs. Give a feasible schedule of jobs with maximum reward

First lets define what is a schedule and what is a feasible schedule:

#### Definition 5.3.2: Feasible Schedule

For a subset  $S$  of jobs:

- ① A schedule is an ordering of  $S$
- ② A feasible schedule is one where one job in  $S$  gets finished by deadline.
- ③ A set  $S \subseteq J$  is feasible if  $S$  has a feasible schedule.

Now for any  $S \subseteq J$ , and  $t \in \mathbb{Z}_+$ , define  $N_t(S) = \{j \in S : d_j \leq t\}$ . Then we have the following lemma:

#### Lemma 5.3.8

The following are equivalent:

- ①  $S$  is feasible
- ②  $\forall t \in \mathbb{Z}_+, |N_t(S)| \leq t$
- ③ The schedule that orders jobs by deadline is feasible

**Proof:**

3  $\implies$  1: This follows naturally

1  $\implies$  2: Suppose not. Then  $\exists t$  such that  $|N_t(S)| > t$ . Then by time  $t$ , greater than  $t$  many jobs have to be completed. But  $S$  is feasible so every job is finished by deadlines and each job takes unit time. Hence by time  $t$ , more than  $t$  jobs can not finished. Hence contradiction.

2  $\implies$  3: The schedule orders the jobs by deadline. We induction on  $t$ . For  $t = 1$  we have  $|N_1(S)| \leq 1$ . Hence by  $t = 1$  at most one job is completed. At  $t = 1$  the jobs are completed within deadline. Suppose till time  $t - 1$  the jobs are completed within deadlines. At time  $t$  we have  $|N_t(S)| \leq t$ . Therefore all the jobs with deadlines  $\leq t$  in  $S$ . So they all can be completed within time  $t$  in any order. Therefore if we complete the jobs with deadline  $< t$  first then also we can complete all the jobs with deadline  $t$  within time  $t$ . Hence at time  $t$  all the jobs are completed within their deadlines. Hence by mathematical induction at time  $t = n$  all the jobs are completed within deadline. Therefore the schedule orders jobs by deadline then it is a feasible schedule. ■

**Lemma 5.3.9**

Consider  $M = (J, \mathcal{I})$  where  $S$  is feasible  $\implies S \in \mathcal{I}$ . Then  $M$  is a matroid. (Assume that no two jobs have same deadline)

**Proof:** Suppose  $D :=$  the maximum of all deadlines. Consider the set

$$\mathcal{L} = \{N_t(J) : t \in [D]\}$$

Then take  $\mathcal{I}' = \{S \subseteq J : |N_t(S)| \leq t \forall t \in [D]\}$ . By Lemma 5.3.4  $M = (J, \mathcal{I}')$  is a laminar matroid. And by Lemma 5.3.8  $\mathcal{I}'$  is the set of feasible schedules. Therefore  $\mathcal{I}' = \mathcal{I}$ . Hence  $M$  is a matroid. ■

**Alternate Proof:**

- ① Downward Closure: If  $S \in \mathcal{I}$  then  $S$  is feasible. Then for any subset  $T$  of  $S$  all the jobs are completed within deadlines since  $S$  is feasible. So  $T \in \mathcal{I}$ .
- ② Exchanges Property: Given  $S, T \in \mathcal{I}$  and  $|T| < |S|$ . Now order  $S$  and  $T$  by deadlines. Let  $j$  be the job with largest deadline that is not in  $S$  i.e.  $j = \max_{i \in S \setminus T} d_i$ . Then we claim that  $T \cup \{j\} \in \mathcal{I}$ .

Now define

$$T^< = \{i \in T : d_i < d_j\} \quad T^> = \{i \in T : d_i > d_j\}$$

And also similarly define

$$S^< = \{i \in S : d_i < d_j\} \quad S^> = \{i \in S : d_i > d_j\}$$

As we defined  $j$  we have  $T^> = S^>$ . Since we have  $|S| > |T|$  we have  $|S^<| \geq |T^<|$ .

Now if  $T \cup \{j\}$  is not feasible then  $\exists t$  such that  $|N_t(T \cup \{j\})| > t$ . Since  $T$  is feasible we have  $|N_t(T)| \leq t$ . Hence  $t \geq d_j$  otherwise  $N_t(T \cup \{j\}) = N_t(T)$ . But then

$$|N_t(T \cup \{j\})| = |T^<| + 1 + |\{i \in T \setminus \{j\} : d_j < d_i \leq t\}| \leq |S^<| + 1 + |\{i \in S \setminus \{j\} : d_j < d_i \leq t\}| = |N_t(S)| \leq t$$

Therefore we obtain  $|N_t(T \cup \{j\})| \leq t$ . Hence contradiction. Therefore  $T \cup \{j\}$  is feasible. ■

# Dijkstra Algorithm with Data Structures

## MINIMUM WEIGHT PATH

**Input:** Directed Graph  $G = (V, E)$ ,  $s \in V$  is source and  $W = \{w_e \in \mathbb{Z}_+ : e \in E\}$

**Question:**  $\forall v \in V - \{s\}$  find minimum weight path  $s \rightsquigarrow v$ .

This is the problem we will discuss in this chapter. In this chapter we will often use the term ‘shortest distance’ to denote the minimum weight path distance. One of the most famous algorithm for finding out minimum weight paths to all vertices from a given source vertex is Dijkstra’s Algorithm

## 6.1 Dijkstra Algorithm

We will assume that the graph is given as adjacency list. Dijkstra Algorithm is basically dynamic programming. Suppose  $\delta(v)$  is the shortest path distance from  $s \rightsquigarrow v$ . Then we have the following relation:

$$\delta(v) = \min_{u:(u,v) \in E} \{\delta(u) + e(u, v)\}$$

And suppose for any vertex  $v \in V - \{s\}$ ,  $dist(v)$  be the distance from  $s$  estimated by the algorithm at any point. This is why Dijkstra’s algorithm maintains a set  $S$  of vertices whose final shortest-path weights from the source  $s$  have already been determined. The algorithm repeatedly selects the vertex  $u \in V - S$  with minimum shortest-path estimate and estimates the distances of neighbors of  $u$ . So here is the algorithm:

---

### Algorithm 16: DIJKSTRA( $G, s, W$ )

---

**Input:** Adjacency Matrix of digraph  $G = (V, E)$ , source vertex  $s \in V$  and weight function  $W = \{w_e \in \mathbb{Z}_+ : e \in E\}$

**Output:**  $\forall v \in V - \{s\}$  minimum weight path from  $s \rightsquigarrow v$

---

```

1 begin
2    $S \leftarrow \emptyset, U \leftarrow V$ 
3    $dist(s) \leftarrow 0, \forall v \in V - \{s\}, dist(v) \leftarrow \infty$ 
4   while  $U \neq \emptyset$  do
5      $u \leftarrow \min_{u \in U} dist(u)$  and remove  $u$  from  $U$ 
6      $S \leftarrow S \cup \{u\}$ 
7     for  $e = (u, v) \in E$  do
8        $dist(v) \leftarrow \min\{dist(v), dist(u) + w(u, v)\}$ 

```

---

Here below we give an example of how the Dijkstra algorithm works:

Figure 6.1: The execution of Dijkstra's algorithm. The source  $s$  is the leftmost vertex. The shortest-path estimates appear within the vertices, and shaded edges indicate predecessor values. Black vertices are in the set  $S$  and at any iteration of while loop the shaded vertex has the minimum value. At any iteration the red edges are the edges considered in minimum weight path from  $s$  using only vertices in  $S$ .

Suppose at any iteration  $t$ , let  $dist_t(v)$  denotes the distance  $v$  from  $s$  calculated by algorithm for any  $v \in V$  and  $S^{(t)}$  denote the content of  $S$  at  $t^{th}$  iteration. In order to show that the algorithm correctly computes the distances we prove the following lemma:

#### Theorem 6.1.1

For each  $v \in S^{(t)}$ ,  $\delta(v) = dist_t(v)$  for any iteration  $t$ .

**Proof:** We will prove this induction. Base case is  $|S^{(1)}| = 1$ .  $S$  grows in size. Then only time  $|S^{(1)}| = 1$  is when  $S^{(1)} = \{s\}$  and  $d(s) = 0 = \delta(s)$ . Hence for base case this is correct.

Suppose this is also true for  $t - 1$ . Let at  $t^{th}$  iteration the vertex  $u \in V - S$  is picked. By induction hypothesis for all  $v \in S^{(t)} - \{u\}$ ,  $dist_t(v) = dist_{t-1}(v) = \delta(v)$ . So we have to show that  $dist_t(u) = \delta(u)$ .

Suppose for contradiction the shortest path from  $s \rightsquigarrow u$  is  $P$  and has total weight  $= \delta(u) = w(P) < dist_t(u)$ . Now  $P$  starts with vertices from  $S^{(t)}$  by eventually leaves  $S$ . Let  $(x, y)$  be the first edge in  $P$  which leaves  $S$  i.e.  $x \in S$  but  $y \notin S$ . By inductive hypothesis  $dist_t(x) = \delta(x)$ . Let  $P_y$  denote the path  $s \rightsquigarrow y$  following  $P$ . Since  $y$  appears before  $u$  we have

$$w(P_y) = \delta(y) \leq \delta(u) = w(P)$$

Now

$$dist_t(y) \leq dist_t(x) + w(x, y)$$

since  $y$  is adjacent to  $x$ . Therefore

$$dist_t(y) \leq dist_t(x) + w(x, y) = \delta(y) \leq dist_t(y) \implies dist_t(y) = \delta(y)$$

Now since both  $u, y \notin S^{(t)}$  and the algorithm picked up  $u$  we have  $\delta(u) < \text{dist}_t(u) \leq \text{dist}_t(y) = \delta(y)$ . But we can not have both  $\delta(y) \leq \delta(u)$  and  $\delta(u) < \delta(y)$ . Hence contradiction. Therefore  $\delta(u) = \text{dist}_t(u)$ . Hence by mathematical induction for any iteration  $t$ , for all  $v \in S^{(t)}$ ,  $\delta(v) = \text{dist}_t(v)$ . ■

Therefore by the lemma after all iterations  $S$  has all the vertices with their shortest distances from  $s$  and henceforth the algorithm runs correctly.

## 6.2 Data Structure 1: Linear Array

## 6.3 Data Structure 2: Min Heap

## 6.4 Amortized Analysis

## 6.5 Data Structure 3: Fibonacci Heap

Instead of keeping just one Heap we will now keep an array of Heaps. We will also discard the idea of binary trees. We will now use a data structure which will take the benefit of the faster time of both the data structure. I.e. The \* is because in Fibonacci Heap the amortized time taken by EXTRACT-MIN is  $O(\log n)$ .

Since Fibonacci heap is an array of heaps there is a *rootlist* which is the list of all the roots of all the heaps in the Fibonacci heap. There is a *min-pointer* which points to the root with the minimum key. For each node in the Fibonacci heap we have a pointer to its parent and we keep 3 variables. The 3 variables are *degree*, *size* and *lost* where *lost* is a Boolean Variable. For any node  $x$  in the Fibonacci heap the  $x.degree$  is the number of children  $x$  has,  $x.size$  is the number of nodes in the tree rooted at  $x$  and  $x.lost$  is 1 if and only if  $x$  has lost a child before. Why any node will lost a child that explanation we will give later. With this set up let's dive into the data structure.

### 6.5.1 Inserting Node

To insert a node we call the FIB-INSERT function and in the function the algorithm initiates the node with setting up all the pointers and variables then add the node to the *rootlist*.

# Kruskal Algorithm with Data Structure

## 7.1 Kruskal Algorithm

## 7.2 Data Structure 1: Array

## 7.3 Data Structure 2: Left Child Right Siblings Tree

## 7.4 Data Structure 3: Union Find

### 7.4.1 Analyzing the Union-Find Data-Structure

We call a node in the union-find data-structure a *leader* if it is the root of the (reversed) tree.

#### Lemma 7.4.1

Once a node stops being a leader (i.e. the node in top of a tree), it can never become a leader again.

**Proof:** A node  $x$  stops being a leader only because of the UNION operation which made  $x$  child of a node  $y$  which is a leader of a tree. From this point on, the only operation that might change the parent pointer of  $x$  is the FIND operation which traverses through  $x$ . Since path-compression only change the parent pointer of  $x$  to point to some other node  $y$ . Therefore the parent pointer of  $x$  will never become equal to itself i.e.  $x$  can never be a leader again. Hence once  $x$  stops being a leader it can never be a leader again. ■

**Lemma 7.4.2**

Once a node stop being a leader then its rank is fixed.

**Proof:** The rank of a node changes only by an UNION operation. But the UNION operation only changes the rank of nodes that are leader after the operation is done. Therefore once a node stops being a leader it's rank will not being changed by an UNION operation. Hence once a node stop being a leader then its rank is fixed. ■

**Lemma 7.4.3**

Ranks are monotonically increasing in the reversed trees, as we travel from a node to the root of the tree.

**Proof:** To show that the ranks are monotonically increasing it suffices to prove that for all edge  $u \rightarrow v$  in the data structure we have  $\text{rank}(u) < \text{rank}(v)$ . ■

**Lemma 7.4.4**

When a node gets rank  $k$  than there are at least  $\geq 2^k$  elements in its subtree.

**Corollary 7.4.5**

For all vertices  $v$ ,  $v.\text{rank} \leq \lfloor \log n \rfloor$

**Corollary 7.4.6**

Height of any tree  $\leq \lfloor \log_2 n \rfloor$

**Lemma 7.4.7**

The number of nodes that get assigned rank  $k$  throughout the execution of the Union-Find data-structure is at most  $\frac{n}{2^k}$ .

Define  $N(r) = \# \text{vertices with rank at least } r$ . Then by the above lemma we have  $N(r) \leq \frac{n}{2^r}$ .

**Lemma 7.4.8**

The time to perform a single find operation when we perform union by rank and path compression is  $O(\log n)$  time.

We will show that we can do much better. In fact we will show that for  $m$  operations over  $n$  elements the overall running time is  $O((n + m) \log^* n)$

**Lemma 7.4.9**

During a single  $\text{FIND}(x)$  operation, the number of jumps between blocks along the search path is  $O(\log^* n)$ .

**Lemma 7.4.10**

At most  $|Block(i)| \leq Tower(i)$  many  $\text{FIND}$  operations can pass through an element  $x$  which is in the  $i^{th}$  block (i.e.  $\text{INDEX}_B(x) = i$ ) before  $x.\text{parent}$  is no longer in the  $i^{th}$  block. That is  $\text{INDEX}_B(x.\text{parent}) > i$ .

**Lemma 7.4.11**

There are at most  $\frac{n}{Tower(i)}$  nodes that have ranks in the  $i^{th}$  block throughout the algorithm execution.

**Lemma 7.4.12**

The number of internal jumps performed, inside the  $i^{th}$  block, during the lifetime of UNION-FIND data structure is  $O(n)$ .

**Theorem 7.4.13**

The number of internal jumps performed by the UNION-FIND data structure overall  $O(n \log^* n)$ .

**Theorem 7.4.14**

The overall time spent on  $m$  FIND operations, throughout the lifetime of a Union-Find data structure defined over  $n$  elements is  $O((n + m) \log^* n)$ .

# Red Black Tree

**Definition 8.1: Perfect Binary Tree**

df

**Definition 8.2: Red Black Tree**

df

**Lemma 8.1**

Every perfect binary tree with  $k$  leaves has  $2k - 1$  nodes (i.e.  $k - 1$  internal nodes).

# Maximum Flow

## 9.1 Flow

Suppose we are given a directed graph  $G = (V, E)$  with a source vertex  $s$  and a target vertex  $t$ . And additionally for every edge  $e \in E$  we are given a number  $c_e \in \mathbb{Z}_0$  which is called the capacity of the edge.

### Definition 9.1.1: Flow

An  $s - t$  flow is a function  $f : E \rightarrow \mathbb{R}_0$  which satisfies the following:

- ①  $\forall e \in E, f(e) \leq c_e$
- ②  $\forall v \in V \setminus \{s, t\}, \sum_{e \in \text{in}(v)} f(e) = \sum_{e \in \text{out}(v)} f(e)$

Also the value of a flow  $f$  is denoted by  $|f| := \sum_{e \in \text{out}(s)} f(e)$ .

Before proceeding into the setup and the problem first we will assume some things

**Assumption.** •  $\text{in}(s) = \emptyset$  i.e. there is no edge into  $s$ .

•  $\text{out}(t) = \emptyset$  i.e. there is no edge out of  $t$ .

• There are no parallel edges

### Lemma 9.1.1

For any flow  $f$ ,  $|f| = \sum_{e \in \text{in}(t)} f(e)$

**Proof:** We have for every edge  $e \in E$ ,  $\exists v \in V$  such that  $e \in \text{in}(v)$  and  $\exists u \in V$  such that  $e \in \text{out}(u)$ . Hence we get

$$\sum_{e \in E} f(e) = \sum_{v \in V} \sum_{e \in \text{in}(v)} f(e) = \sum_{v \in V} \sum_{e \in \text{out}(v)} f(e) \implies \sum_{v \in V} \left[ \sum_{e \in \text{in}(v)} f(e) - \sum_{e \in \text{out}(v)} f(e) \right] = 0$$

Now we know  $\forall v \in V \setminus \{s, t\}, \sum_{e \in \text{in}(v)} f(e) = \sum_{e \in \text{out}(v)} f(e)$ . Therefore we get

$$\sum_{v \in V} \left[ \sum_{e \in \text{in}(v)} f(e) - \sum_{e \in \text{out}(v)} f(e) \right] = 0 \implies \sum_{v \in \{s, t\}} \left[ \sum_{e \in \text{in}(v)} f(e) - \sum_{e \in \text{out}(v)} f(e) \right] = 0 \implies \sum_{e \in \text{out}(s)} f(e) - \sum_{e \in \text{in}(t)} f(e)$$

Hence we have  $|f| = \sum_{e \in \text{in}(t)} f(e)$ . ■

## MAX FLOW

**Input:** A directed graph  $G = (V, E)$  with source vertex  $s$  and target vertex  $t$  and for all edge  $e \in E$  capacity of the edge  $c_e \in \mathbb{Z}_+$

**Question:** Given such a graph and its capacities find an  $s - t$  flow which has the maximum value

**Example 9.1.1**

Consider the following directed graph with capacities:  $V = \{s, t, u, v\}$ ,  $c_{s,u} = 2, c_{s,v} = c_{u,t} = c_{v,t} = c_{u,v} = 1$ . Firstly the following function:  $f' : f'(s, u) = 2 = f(u, t)$ . It is not a flow since  $f(u, t) = 2 > 1 = c_{u,t}$ . Now we define three different flow functions:

- $f$ :  $f(s, u) = f(u, v) = f(v, t) = 1$  and otherwise 0. Therefore  $|f| = 1$
- $g$ :  $g(s, u) = g(u, t) = 1, g(s, v) = g(v, t) = 1$  and otherwise 0. Therefore  $|g| = 2$
- $h$ :  $h(s, u) = 2, h(u, t) = h(u, v) = h(v, t) = 1$  and otherwise 0. Therefore  $|h| = 2$

Notice here  $g$  and  $h$  has the maximum flow value.

## 9.2 Ford-Fulkerson Algorithm

### Definition 9.2.1: Residual Graph

Given a directed graph  $G = (V, E)$  and capacities  $C_e$  for all  $e \in E$  and an  $s - t$  flow  $f$  the residual graph  $G_f = (V, E_f)$  has the edges with the following properties:

- ① If  $(u, v) \in E$  and  $f(u, v) > 0$  then  $(v, u) \in E_f$  and  $c_{v,u}^f = f(u, v)$ . Such an edge is called a *backward* edge.
- ② If  $(u, v) \in E$  and  $f(u, v) < c_{u,v}$  then  $(u, v) \in E_f$  and  $c_{u,v}^f = c_{u,v} - f(u, v)$ . It is called *forward* edge.

### Algorithm 17: FORD-FULKERSON

**Input:** Directed graph  $G = (V, E)$ , source  $s$ , target  $t$  and edge capacities  $C_e$  for all  $e \in E$

**Output:** Flow  $f$  with maximum value

```

1 begin
2   for  $e \in E$  do
3      $f(e) = 0$ 
4   while  $\exists s \rightsquigarrow t$  path  $P$  in  $G_f$  do
5      $\delta \leftarrow \min_{e \in P} \{c_e^f\}$  for  $e = (u, v) \in P$  do
6       if  $e$  is Forward Edge then
7          $f(u, v) \leftarrow f(u, v) + \delta$ 
8       else
9          $f(u, v) \leftarrow f(v, u) - \delta$ 

```

We call one iteration of the While loop at line 4 *Flow Augmentation*.

**Lemma 9.2.1**

At any iteration the  $f'$  obtained after the flow augmentation of the flow  $f$  is a valid flow

**Proof:** At any iteration let  $P$  be the path from  $s \rightsquigarrow t$  and  $\delta = \min_{e \in P} c_f(e)$ . Let  $f'$  be the new function such that for each  $(u, v) \in P$  if  $(u, v)$  is forward edge in  $G_f$  then  $f'(u, v) = f(u, v) + \delta$  and if  $(u, v)$  is backward edge in  $G_f$  then  $f'(v, u) = f(v, u) - \delta$  and for other edges  $e \in E \setminus P$ ,  $f'(e) = f(e)$ .

Now since  $\delta = \min_{e \in P} c_f(e)$ ,  $c_f(e) \geq \delta$  for all  $e \in P$ . Hence if  $(u, v)$  is backward edge then  $(v, u) \in E$  and  $c_f(u, v) = f(u, v)$ . Hence  $f'(v, u) = f(v, u) - \delta \geq 0$ . Therefore for all  $e \in E$ ,  $f'(e) \geq 0$ .

Now first we will show  $f'(e) \leq c_e$  for all  $e \in E$ . If  $(u, v) \in P$  is a forward edge then  $(u, v) \in E$  and  $c_f(u, v) = c_{u,v}f(u, v)$ . Therefore  $f'(u, v) = f(u, v) + \delta \leq f(u, v) + c_{u,v} - f(u, v) = c_{u,v}$ . Now if  $(u, v) \in P$  is a backward edge then  $(v, u) \in E$  and  $c_f(u, v) = f(u, v)$ . Therefore  $f'(u, v) = f(u, v) - \delta \leq f(u, v) \leq c_{u,v}$ . For other edges  $e \in E \setminus P$ ,  $f'(e) = f(e) \leq c_e$ . Therefore  $f'(e) \leq c_e$  for all  $e \in E$ .

Now we will prove for all  $v \in V \setminus \{s, t\}$ ,  $\sum_{e \in in(v)} f'(e) = \sum_{e \in out(v)} f'(e)$ . If  $v$  is not in the path  $P$  in  $G_f$  then,  $f'(e) = f(e)$  for all edges  $e \in in(v) \cup out(v)$ . Hence the condition is satisfied for such vertices. Suppose  $v$  is in the path  $P$ . Then there are two edges  $e_1$  and  $e_2$  in  $P$  which are incident on  $v$ . If both are forward edges or both are backward edges then one of them is in  $in(v)$  and other one is in  $out(v)$ . WLOG suppose  $e_1 \in in(v)$  and  $e_2 \in out(v)$  we have

$$\sum_{e \in in(v)} f'(e) = \sum_{e \in in(v) \setminus \{e_1\}} f(e) + f(e_1) \pm \delta = \sum_{e \in out(v) \setminus \{e_2\}} f(e) + f(e_2) \pm \delta = \sum_{e \in out(v)} f'(e)$$

If one of  $e_1, e_2$  forward edge and other one is backward edge then either  $e_1, e_2 \in in(v)$  (when  $e_1$  is forward and  $e_2$  is backward) or  $e_1, e_2 \in out(v)$  (when  $e_1$  is backward and  $e_2$  is forward). Now if  $e_1, e_2 \in in(v)$ ,  $f'(e_1) + f'(e_2) = f(e_1) + \delta + f(e_2) - \delta = f(e_1) + f(e_2)$  and if  $e_1, e_2 \in out(v)$  then  $f'(e_1) + f'(e_2) = f(e_1) - \delta + f(e_2) + \delta = f(e_1) + f(e_2)$ . Hence

$$\sum_{e \in in(v)} f'(e) = \sum_{e \in in(v)} f(e) = \sum_{e \in out(v)} f(e) = \sum_{e \in out(v)} f'(e)$$

Hence  $f'$  is a valid flow. ■

**Lemma 9.2.2**

At any iteration Given  $G_f$  if the flow,  $f'$  obtained after flow augmentation of  $f$  by  $\delta$  then

$$|f'| = |f| + \delta$$

**Proof:** Since we augment flow along an  $s \rightsquigarrow t$  path, the first edge of the path is always in  $out(s)$ . Let the first edge is  $e = (s, u)$ . Now  $e$  has to be a forward edge because otherwise  $(u, s) \in E$  and then there is an incoming edge in  $G$  which is not possible. Hence

$$|f'| = \sum_{e \in out(s)} f'(e) = \sum_{e \in out(s) \setminus \{e\}} f(e) + f'(e) = \sum_{e \in out(s) \setminus \{e\}} f(e) + f(e) + \delta = \sum_{e \in out(s)} f(e) + \delta = |f| + \delta$$

Hence we have the lemma. ■

**Lemma 9.2.3**

At every iteration of the Ford-Fulkerson Algorithm the flow values and the residual capacities of the residual graph are non-negative integers.

**Proof:** Initial flow and the residual capacities are non-negative integers. Let till  $i^{th}$  iteration the flow values and the residual capacities were non-negative integers. Let the flow after  $i^{th}$  iteration was  $f$ . Hence  $\forall e \in E, f(e) \in \mathbb{Z}_0$ . Therefore in the  $G_f$  for all  $e \in E_f$ ,  $c_f(e) \in \mathbb{Z}_0$ . Hence  $\delta \in \mathbb{Z}_0$ . Therefore  $\forall e \in E, f'(e) \in \mathbb{Z}_0$ . And therefore for all  $e \in E_{f'}$  where  $G_{f'}$  is the residual graph of the flow  $f'$ ,  $c_{f'}(e) \in \mathbb{Z}_0$ . Hence by mathematical induction the lemma follows. ■

At any iteration let  $P$  be the path from  $s \rightsquigarrow t$ . Then for all  $e \in P$ ,  $c_f(e) > 0$ . Therefore  $\delta = \min_{e \in P} c_f(e) \geq 1$ . Therefore the algorithm must stop in at most  $\sum_{e \in out(s)} c_e$  since we can have the value of a flow to be at max the value of the sum of capacities of edges in  $out(s)$  and therefore we can increase the flow at max that many times.

#### Lemma 9.2.4

If  $f$  is a max flow then there is no  $s \rightsquigarrow t$  path in  $G_f$ .

**Proof:** Suppose there is an  $s \rightsquigarrow t$  path  $P$  in  $G_f$ . We will show that then  $f$  is not a max flow following the algorithm. Then  $\forall e \in P$ ,  $c_f(e) > 0$ . Hence  $\delta = \min_{e \in P} c_f(e) \geq 1$ . Now after the flow augmentation process of  $f$  by  $\delta$  we get a new valid flow  $f'$  by Lemma 9.2.1 and by Lemma 9.2.2 we have  $|f'| = |f| + \delta > |f|$ . Hence  $f$  is not a maximum flow. Hence contradiction. Therefore there is no  $s \rightsquigarrow t$  path in  $G_f$ . ■

### 9.2.1 Max Flow Min Cut

#### Definition 9.2.2: Cut Set

For a graph  $G = (V, E)$  and a subset  $A \subseteq V$ , the cut  $(A, V \setminus A)$  is a bipartition of  $V$  where the edges  $E_A$  of the graph  $G_A = (A, V \setminus A, E_A)$  is the set  $E_A = E \cap (A \times (V \setminus A))$ .

Now if  $s, t$  are two vertices of  $G$  then an  $s - t$  Cut  $(A, V \setminus A)$  is a cut such that  $s \in A$  and  $t \in V \setminus A$ .

Now we define for a cut  $(A, V \setminus A)$  the *Capacity of the Cut*  $(A, V \setminus A) = \sum_{e \in E_A} c_e$ . For an  $s - t$  cut  $(A, V \setminus A)$  we denote the capacity of the cut by  $cap(A)$ . A *Min  $s - t$  Cut* is a  $s - t$  cut of minimum capacity. Then we have the following relation between cut and flow.

#### Lemma 9.2.5

Given a graph  $G = (V, E)$ ,  $s, t, c_e \in \mathbb{Z}_0$  for all  $e \in E$  for any flow  $f$  and a  $s - t$  cut  $(A, V \setminus A)$

$$|f| \leq cap(A)$$

**Proof:** Given  $f$  and the  $s - t$  cut  $(A, V \setminus A)$  we have

$$\begin{aligned} |f| &= \sum_{e \in out(s)} f(e) \\ &= \sum_{v \in A} \left[ \sum_{e \in out(v)} f(e) - \sum_{e \in in(v)} f(e) \right] \\ &= \sum_{\substack{e=(u,v), \\ u \in A, v \notin A}} f(e) - \sum_{\substack{e=(u,v), \\ u \notin A, v \in A}} f(e) && \text{[Edges for both endpoints in } A \text{ are canceled out]} \\ &= \sum_{e \in out(A)} f(e) - \sum_{e \in in(A)} f(e) \\ &\leq \sum_{e \in out(A)} f(e) \leq \sum_{e \in out(A)} c_e = cap(A) \end{aligned}$$

Hence we have the lemma. ■

Having this lemma we have for any flow  $f$  and  $s - t$  cut  $(A, V \setminus A)$  we have

$$|f| \leq cap(A) \implies \max_f |f| \leq \min_{s-t \text{ cut } (A, V \setminus A)} cap(A)$$

So we have the following theorem that the value of maximum flow is equal to the capacity of minimum cut.

**Theorem 9.2.6 Max Flow Min Cut**

Given a graph  $G = (V, E)$ ,  $s, t, c_e \in \mathbb{Z}_0$  for all  $e \in E$ . Then the following are equivalent:

- (1)  $f$  is a maximum flow.
- (2) There is no  $s \rightsquigarrow t$  path in  $G_f$
- (3) There exists an  $s - t$  cut of capacity  $|f|$

**Proof:**

(1)  $\implies$  (2): This is by [Lemma 9.2.4](#).

(2)  $\implies$  (3): We are given a flow  $f$  such that there is no  $s \rightsquigarrow t$  path in  $G_f$ . We will construct a  $s - t$  cut which has the capacity  $|f|$ . Now take  $A$  to be all the vertices reachable from  $s$  in  $G_f$ . This is a valid  $s - t$  cut since  $s \in A$  and as there is no  $s \rightsquigarrow t$  path in  $G_f$ ,  $t \notin A$ . Now

$$|f| = \sum_{e \in \text{out}(A)} f(e) - \sum_{e \in \text{in}(A)} f(e)$$

Now  $\forall e = (u, v) \in E$  where  $u \in A$  and  $v \notin A$  we have  $c_{u,v} = f(u, v) \implies c_{u,v} - f(u, v) = 0$  since otherwise  $c_{u,v} - f(u, v) \neq 0 \implies c_{u,v} > f(u, v) \implies (u, v) \in E_f$  and therefore  $v$  is reachable from  $s$  but  $v \notin A$ , contradiction. Therefore  $(u, v)$  is a backward edge and hence  $f(u, v) = 0$ . Now  $\forall e = (u, v) \in E$  where  $u \notin A$  and  $v \in A$  we have  $f(u, v) = 0$  since otherwise  $f(u, v) > 0 \implies (v, u) \in E_f$  and therefore  $u$  is reachable from  $s$  but  $u \notin A$ , contradiction. Hence we have

$$|f| = \sum_{e \in \text{out}(A)} f(e) - \sum_{e \in \text{in}(A)} f(e) = \sum_{e \in \text{out}(A)} c_e = \text{cap}(A)$$

(3)  $\implies$  (1): Now by [Lemma 9.2.5](#) we have for any flow  $f$  and  $s - t$  cut

$$|f| \leq \text{cap}(A) \implies \max_f |f| \leq \min_{s-t \text{ cut } (A, V \setminus A)} \text{cap}(A)$$

Now given  $f$  there exists an  $s - t$  cut of capacity  $|f|$ . Hence  $f$  is a max flow. ■

Hence at the end of the [Ford-Fulkerson Algorithm](#) let the flow returned by the algorithm is  $f$ . The algorithm terminates when there is no  $s \rightsquigarrow t$  path in  $G_f$ . Hence by [Max Flow Min Cut Theorem](#) we have  $f$  is a maximum flow. This completes the analysis of the Ford-Fulkerson Algorithm.

Since the capacities of the edges can be very large we want an algorithm return the maximum flow with running time  $\text{poly}(n, m, \log c_e)$  where  $n$  is the number of vertices and  $m$  is number of edges and  $\log c_e$  basically means number of bits at most needed to represent the capacities.

But Ford-Fulkerson algorithm takes does not run in  $\text{poly}(n, m, \log c_e)$  instead  $\text{poly}(n, m, c_e)$  as the while loop in the algorithm takes  $\text{poly}(c_e)$  many iterations. For example in the following graph: it takes around 100 steps

and in general Ford-Fulkerson takes  $O(|f_{\max}|)$  time. For this reason we will now discuss a modification of the Ford-Fulkerson Algorithm which takes  $\text{poly}(n, m, \log c_e)$  time, Edmonds-Karp Algorithm.

### 9.2.2 Edmonds-Karp Algorithm

To get a  $\text{poly}(n, m, \log c_e)$  time algorithm we will always pick the shortest  $s \rightsquigarrow t$  path in the residual graph. This algorithm is known as the Edmonds-Karp Algorithm

Suppose  $f_i$  be the total flow after  $i^{\text{th}}$  iteration. And  $G_{f_i}$  be the residual graph with respect  $f_i$ . Then  $f_0(e) = 0$  for all  $e \in E$  and  $G_{f_0} = G$ . Also suppose  $\text{dist}_i(v) = \text{Shortest } s \rightsquigarrow v \text{ path distance in the residual graph } G_{f_i}$ . Hence  $\text{dist}_i(s) = 0$  for all  $i$  and  $\text{dist}_i(t) = \infty$  at the end of the algorithm.

**Note:-**

In  $i^{\text{th}}$  iteration of the Ford-Fulkerson Algorithm or Edmonds-Karp Algorithm if  $P$  is the  $s \rightsquigarrow t$  in the residual graph  $G_{f_i}$  where  $e = (u, v) \in P$  and  $c_{f_i}(u, v) = \delta = \min_{e \in P} c_{f_i}(e)$  then the edge  $(u, v)$  is not present in the next residual graph  $G_{f_{i+1}}$ . Thus at least one edge disappears in each iteration of Ford-Fulkerson or Edmonds-Karp Algorithm.

Now we will prove following two lemmas which will help us to prove that the Edmond-Karp algorithm takes  $O(mn)$  iterations.

**Lemma 9.2.7**

At any iteration  $i$ ,  $\forall v \in V$ ,  $\text{dist}_i(v) \leq \text{dist}_{i+1}(v)$

**Proof:** Suppose this is not true. Then let  $i$  be the first iteration in which there exists a vertex  $v \in V$  such that  $\text{dist}_i(v) > \text{dist}_{i+1}(v)$ . We pick such  $v$  which minimizes  $\text{dist}_{i+1}(v)$ . Consider the shortest path  $P$  from  $s \rightsquigarrow v$  in  $G_{f_{i+1}}$ . Hence length of  $P$ ,  $|P| = \text{dist}_{i+1}(v)$ . Let  $(u, v)$  be the last edge of  $P$ .

Then

$$\text{dist}_{i+1}(v) = \text{dist}_{i+1}(u) + 1 \geq \text{dist}_i(u) + 1$$

Here the last inequality follows because  $v$  is the vertex which has the minimum  $\text{dist}_{i+1}(v)$  among all the vertices  $w \in V$  which follows  $\text{dist}_i(w) > \text{dist}_{i+1}(w)$ . Now we will analyze case wise.

- **Case 1:**  $(u, v) \in E_{f_i}$ . Then

$$\text{dist}_i(v) \leq \text{dist}_i(u) + 1 \leq \text{dist}_{i+1}(v)$$

But this is not possible since  $\text{dist}_i(v) > \text{dist}_{i+1}(v)$ .

- **Case 2:**  $(u, v) \notin E_{f_i}$ . Then  $(v, u) \in E_{f_i}$ . Since  $(u, v) \in E_{f_{i+1}}$  then we must have sent flow along  $(v, u)$ . Since we take the shortest  $s \rightsquigarrow t$  path in  $G_{f_i}$  in the algorithm we have  $\text{dist}_i(u) = \text{dist}_i(v) + 1$ . But then

$$\text{dist}_i(u) \leq \text{dist}_{i+1}(v) - 1 \implies \text{dist}_{i+1}(v) \geq \text{dist}_i(v) + 2$$

But this is not possible.

Hence contradiction  $\nexists$  Therefore for all iterations  $i$ , for all vertices  $v \in V$ ,  $\text{dist}_i(v) \leq \text{dist}_{i+1}(v)$ . ■

**Lemma 9.2.8**

For any edge  $e = (u, v) \in E$  the number of iterations where either  $(u, v)$  appears or  $(v, u)$  appears is at most  $O(n)$  i.e.

$$\left| \{i: (u, v) \notin G_{f_i}, (u, v) \in G_{f_{i+1}}\} \right| + \left| \{i: (v, u) \notin G_{f_i}, (v, u) \in G_{f_{i+1}}\} \right| = O(n)$$

**Proof:** Following the proof of [Lemma 9.2.7](#) in the second case we showed if  $(u, v) \notin G_{f_i}$  but  $(u, v) \in G_{f_{i+1}}$  then  $\text{dist}_{i+1}(v) \geq \text{dist}_i(v) + 2$ . Hence the distance increases by at least 2. Now this can happen at most  $O(n)$  many times since  $\forall i$ ,  $\text{dist}_i(v) \leq n - 1$ . Hence the number of iterations where either  $(u, v)$  appears or  $(v, u)$  appears is at most  $O(n)$ . ■

With this this lemma we will prove that the Edmonds-Karp Algorithm takes  $O(mn)$  iterations.

**Theorem 9.2.9**

Edmonds-Karp Algorithm terminates in  $O(mn)$  many iterations.

**Proof:** For  $k$  iterations at least  $k$  edges must disappear. Since each edge can reappear  $O(n)$  times by Lemma 9.2.8, it can disappear at most  $O(n)$  many times. In each iteration at least one edge disappears. Now after  $O(mn)$  iterations number of disappearances is at most  $O(mn)$ . But after  $O(mn)$  many disappearances there are no edge remaining and therefore there is no  $s \rightsquigarrow t$  path. Hence the algorithm terminates. Therefore the Algorithm terminates in  $O(mn)$  iterations. ■

Hence Edmond-Karp Algorithm takes  $O(m^2n) \text{poly}(\log c_e) = O\left(m^2n \log^{O(1)}(c_e)\right)$  time since it takes  $O(mn)$  iterations and in each iteration it finds the shortest  $s \rightsquigarrow t$  path in  $G_{f_i}$  in  $O(m)$  time and in each iteration it does addition and subtraction and finds minimum of the capacities which takes polynomial of the bits needed to represent them time.

### 9.3 Preflow-Push/Push-Relabel Algorithm

In this algorithm we will maintain something called “Preflow” which is not a valid flow. Unlike Ford-Fulkerson, Edmonds-Karp it does not maintain a  $s \rightsquigarrow t$  path in the residual graph and the algorithm stops when the preflow is actually a valid flow.

**Definition 9.3.1: Preflow**

Given a graph  $G = (V, E)$  and the edge capacities  $c_e$ , a function  $f : E \rightarrow \mathbb{R}_0$  is a preflow if it satisfies:

- ①  $\forall e \in E, f(e) \leq c_e.$
- ②  $\forall v \in V \setminus \{s\}, \sum_{e \in \text{in}(v)} f(e) \geq \sum_{e \in \text{out}(v)} f(e)$

Notice here unlike the definition of Flow here in the second criteria we need  $\sum_{e \in \text{in}(v)} f(e) \geq \sum_{e \in \text{out}(v)} f(e)$  instead of  $\sum_{e \in \text{in}(v)} f(e) = \sum_{e \in \text{out}(v)} f(e).$

Now define for all  $v \in V$  and for all preflow  $f$ ,  $\text{excess}_f(v) = \sum_{e \in \text{in}(v)} f(e) - \sum_{e \in \text{out}(v)} f(e)$ . If  $f$  is a preflow then  $\text{excess}_f(s) \leq 0$  and  $\forall v \in V \setminus \{s\}, \text{excess}_f(v) \geq 0$

**Lemma 9.3.1**

For all preflow  $f$

$$\sum_{v \in V} \text{excess}_f(v) = 0$$

**Proof:**

$$\begin{aligned} \sum_{v \in V} \text{excess}_f(v) &= \sum_{v \in V} \left[ \sum_{e \in \text{in}(v)} f(e) - \sum_{e \in \text{out}(v)} f(e) \right] \\ &= \sum_{v \in V} \sum_{e \in \text{in}(v)} f(e) - \sum_{v \in V} \sum_{e \in \text{out}(v)} f(e) \\ &= \sum_{e \in E} f(e) - \sum_{e \in E} f(e) = 0 \end{aligned}$$

Now for each  $v \in V$  we assign a label  $l(v) \in \mathbb{Z}_0$ . The algorithm then sends flow from  $u \rightarrow v$  if  $l(v) = l(u) - 1$ .

**Algorithm 18:** PREFLOW-PUSH**Input:** Directed graph  $G = (V, E)$ , source  $s$ , target  $t$  and edge capacities  $C_e$  for all  $e \in E$ **Output:** Flow  $f$  with maximum value

```

1 begin
2   Initially  $\forall e = (s, u) \in E, f(e) = c_e$  and  $f(e) = 0$  for all other edges.
3    $l(s) \leftarrow n$ 
4   for  $v \in V \setminus \{s\}$  do
5      $l(v) \leftarrow 0$ 
6   while  $\exists v \neq t, excess_f(v) > 0$  do
7     if  $\exists u$ , such that  $(v, u) \in E_f$  and  $l(u) = l(v) - 1$  then
8        $\delta \leftarrow \min \{excess_f(v), c_f(v, u)\}$ 
9       if  $(v, u)$  is Forward Edge then
10         $f(v, u) \leftarrow f(v, u) + \delta$ 
11      else
12         $f(u, v) \leftarrow f(u, v) - \delta$ 
13      else
14         $l(v) \leftarrow l(v) + 1$  //Relabeling

```

In the algorithm in line 8 if  $\delta = c_f(v, u)$  then we call it *saturating push* and if  $\delta = excess_f(v)$  then we call it *non-saturating push*.

Now we will show an example of how the algorithm on a graph. We will start the algorithm with the following graph:

Below we will show change of the residual graph and preflow in each iteration of the WHILE loop:

## • Step 1:

Since  $excess_f(v) = 6 > 0$ . So in first iteration  $v$  is taken. Since there is no edge  $(v, u)$  with  $l(u) = l(v) - 1$ , label of  $v$  got increased

## • Step 2:

Since  $excess_f(v) = 2 > 0$ , in second iteration again  $v$  is selected. There is an edge  $(v, t)$  with  $l(t) = 0 = l(v) - 1 = 1 - 1$ . Now  $\delta = c_f(v, t) = 4$ . Hence saturating push. The preflow gets updated,  $f(s, v) = 6, f(v, t) = 4$ .

## • Step 5:

Since  $excess_f(v) = 2 > 0$ , in next 3 iterations again  $v$  is selected. Since there is no edge  $(v, u)$  with  $l(u) = l(v) - 1$ , label of  $v$  gets increased every time. Which becomes 4 after 3 iterations.

- Step 6:

Since  $excess_f(v) = 2 > 0$ , in this iteration again  $v$  is selected. There is an edge  $(v, s)$  with  $l(t) = 3 = l(v) - 1 = 4 - 1$ . Now  $\delta = excess_f(v, s) = 2$ . Hence it's non-saturating push. So the preflow gets updated  $f(s, v) = 6 - 2 = 4, f(v, t) = 4$ . Now it's a valid flow. Now there is no vertex with positive excess. Hence the algorithm stops.

**Observation 9.1.** Labels are monotone non-decreasing.

**Observation 9.2.** For every iteration  $f$  is always a preflow. The proof is similar to Lemma 9.2.1 but use inequalities.

**Observation 9.3.**  $\sum_{v \in V} excess_f(v) = 0$  and  $\forall v \in V \setminus \{s\}, excess_f(v) \geq 0$ . Hence  $excess_f(s) \leq 0 \implies l(s)$  is unchanged.

Now suppose  $f^i$  denote the preflow after the  $i^{th}$  iteration of the algorithm. Then

$$f^0(e) = \begin{cases} c_e & \text{when } e = (s, u) \\ 0 & \text{otherwise} \end{cases}$$

Now we will show the correctness of the algorithm.

### Lemma 9.3.2

$\forall v \in V, \forall i, excess_{f^i}(v) > 0 \implies \exists v \rightsquigarrow s$  in  $G_{f^i}$

**Proof:** First we fix  $v$  and  $i$  such that  $excess_{f^i} > 0$ . Let  $X$  be the set of vertices reachable from  $v$  in  $G_{f^i}$ . Now

$$\sum_{u \in X} excess_{f^i}(u) = \sum_{u \in X} \left[ \sum_{e \in in(v)} f^i(e) - \sum_{e \in out(v)} f^i(e) \right] = \sum_{e \in in(X)} f^i(e) - \sum_{e \in out(X)} f^i(e)$$

Now if  $\sum_{e \in in(X)} f^i(e) > 0$  then  $\exists e = (u', u) \in E$  such that  $u' \notin X$  and  $u \in X$  and  $f^i(e) > 0$ . Then the backward edge  $(u, u') \in E_{f^i}$ . Then  $u'$  is reachable from  $v$  in  $G_{f^i}$ . But  $u' \notin X$ . Contradiction. Therefore  $\sum_{e \in in(X)} f^i(e) = 0$ . Hence

$$\sum_{u \in X} excess_{f^i}(u) = \sum_{e \in in(X)} f^i(e) - \sum_{e \in out(X)} f^i(e) \leq 0$$

But from Observation 9.3 we have  $\forall w \in V \setminus \{s\}, excess_{f^i}(w) \geq 0$ . But at the same time  $\sum_{u \in X} excess_{f^i}(u) \leq 0$  and  $excess_{f^i}(v) > 0$ . Hence  $\exists$  a vertex  $u \in X$  such that  $excess_{f^i}(u) < 0$ . But we know only vertex with negative excess is  $s$ . Therefore  $s \in X$ . Hence  $s$  is reachable from  $v$ . ■

### Lemma 9.3.3

$\forall i$ , if  $(u, v) \in G_{f^i}$  then  $l(v) \geq l(u) - 1$ .

**Proof:** We will prove this using induction on  $i$ . Initially  $l(s) = n$  and  $l(v) = 0$  for all  $v \in V \setminus \{s\}$ . Hence for all edges  $(u, v)$  where  $u, v \neq s$  this is satisfied. All the other edges incident on  $s$  are in  $in(s)$  in the residual graph. And  $l(s) = n \geq l(u) = 0$ . Therefore the base case is followed.

Now suppose the condition is true for  $f^{i-1}$ . Now in the  $i^{th}$  iteration suppose the selected vertex is  $v \in V \setminus \{t\}$  with  $excess_{f^{i-1}} > 0$ . Now there are two possible cases.

- **Case 1:** If the step is relabeling then  $f^{i-1} = f^i, G_{f^{i-1}} = G_{f^i}$  but  $v$  is relabeled by  $l(v) + 1$ . Now for any edge  $e = (u, v) \in in(v)$  by Inductive Hypothesis  $l(v) \geq l(u) - 1 \implies l(v) + 1 \geq l(u) - 1$ . Now consider any edge  $e = (v, w) \in out(v)$ . By Inductive Hypothesis we have  $l(w) \geq l(v) - 1$ . Now if  $l(w) = l(v) - 1$  then we would have pushed flow along the edge  $(v, w)$ . Since that is not the case we have  $l(w) > l(v) - 1$ . Therefore  $l(w) \geq (l(v) + 1) - 1$ . Hence the condition is satisfied.

- **Case 2:** If the step is pushing flow then suppose we push flow along the edge  $(v, w) \in E_{f^{i-1}}$  and  $l(w) = l(v) - 1$ . Now if we push flow along the edge  $(v, w)$  we might introduce the reverse edge  $(w, v)$  in  $G_{f^i}$ . In that case  $l(v) = l(w) + 1 \geq l(w) - 1$ . Hence the condition is satisfied.

Therefore by mathematical induction  $\forall i, \forall (u, v) \in E_{f^i}, l(v) \geq l(u) - 1$ . ■

#### Corollary 9.3.4

There is no  $s \rightsquigarrow t$  path in  $G_{f^i}$  in any iteration  $i$ . Thus when the algorithm terminates  $f$  is a max flow.

**Proof:** Now  $l(s) = n$  and  $l(t) = 0$ . We fix  $v$  and  $i$ . If there is a  $s \rightsquigarrow v$  path in  $G_{f^i}$  then length of the path is at most  $n - 1$ . For each edge in the path the label decreases by at most 1 by Lemma 9.3.3. Hence  $l(v) \geq 1$ . Therefore for every vertex  $v \in V$ , reachable from  $s$  we have  $l(v) \geq 1$ . But  $l(t) = 0$ . Hence  $t$  is not reachable from  $s$ . Hence if the algorithm terminates, and if  $f$  is a valid flow then by Max Flow Min Cut Theorem it is a max flow. ■

#### Corollary 9.3.5

$\forall v \in V, \forall i, l(v) \leq 2n$ .

**Proof:** Suppose  $\exists v, i$  such that  $l(v) = 2n$  and  $excess_{f^i}(v) > 0$ . By Lemma 9.3.2 there exists an  $v \rightsquigarrow s$  path in  $G_{f^i}$ . Now by Lemma 9.3.3 for each edge in the path the label decreases by at most 1 and the length of the path is at most  $n - 1$ . Since  $l(v) = 2n$ ,  $l(s) \geq n + 1$ . But we know  $l(s)$  for all  $i$  by Observation 9.3. Hence contradiction. Therefore for all  $v \in V$  and  $\forall i, l(v) \leq 2n$ . ■

#### Corollary 9.3.6

Total number relabeling operations is  $\leq 2n^2$

**Proof:** By Corollary 9.3.5 each vertex label can be at most  $2n$ . So total number of relabeling operations done in the algorithm is at most  $2n^2$ . ■

Now we need a bound on the number of push operations. We will count separately the number of Saturating Pushes and number of Non-Saturating Pushes.

#### Lemma 9.3.7

Total number of saturating pushes is  $\leq 2mn$

**Proof:** We first fix an edge  $(v, w)$ . Now we will count the number of saturating pushes along  $(v, w)$ . Then  $\delta = c_f(v, w)$ . Now consider the scenario of two consecutive saturating pushes along  $(v, w)$ . When the first saturating push along  $(v, w)$  occurred we have  $l(w) = l(v) - 1$ . Now if  $(v, w)$  is forward edge then  $\delta = c_f(v, w) = c_{v,w} - f(v, w)$ . Then new flow along  $(v, w)$  is  $f(v, w) + c_f(v, w) = c_{v,w}$ . Hence the edge  $(v, w)$  vanishes and the flow along  $(w, v)$  is  $c_{v,w}$ . If  $(v, w)$  is a backward edge then  $\delta = c_f(w, v) = f(w, v)$ . Hence then new flow along  $(w, v)$  is  $f(w, v) - \delta = 0$ . Hence again the  $(w, v)$  edge vanishes and the flow along  $(w, v)$  is  $f(w, v)$ .

Therefore after a saturated push along  $(v, w)$  the edge vanishes and the  $(w, v)$  edge is there. Hence in order for another push along  $(v, w)$  the algorithm must push flow along  $(w, v)$ . And this happens when we have the new labels of

$v, w$  follow the condition  $l'(w) = l'(v) + 1$ . Since by [Observation 9.1](#) the labels never decreases in order for  $l(w) = l(v) + 1$  the label of  $v$  must increase by at least 2.

Now starting from  $l(v) = 0$  we have by [Lemma 9.3.5](#)  $l(v) \leq 2n$  and for each saturating push along  $(v, w)$  the  $l(v)$  increase by 2. Hence at most  $n$  many saturating pushes occurred along  $(v, w)$ . Now in the original graph since there are  $m$  edges the total number of saturating pushes is  $\leq 2mn$ . ■

Now we will count the number of non-saturating pushes. For such pushes along any edge  $(v, u)$  the  $excess_f(v)$  goes to 0. We define the potential function for a preflow  $f$ ,

$$\Phi(f) = \sum_{v: excess_f(v) > 0} l(v)$$

Now  $\Phi(f) \geq 0$  for all preflow  $f$  and initially at the start of the algorithm  $\Phi(f^0) = 0$ .

### Lemma 9.3.8

For each non-saturating push  $\Phi(f)$  decreases by at least 1.

**Proof:** Suppose at any iteration  $i$  a non-saturating push occur along an edge  $(v, w)$ . Therefore  $l(w) = l(v) - 1$ . We will show that  $\Phi(f^i) \leq \Phi(f^{i-1}) - 1$ . We have  $\delta = excess_{f^{i-1}}(v)$ . Now if  $(v, w)$  is a forward edge then new flow along  $(v, w)$  is  $f^i(v, w) = f^{i-1}(v, w) + excess_{f^{i-1}}(v)$ . Since  $(v, w) \in out(v)$

$$excess_{f^i}(v) = \sum_{e \in in(v)} f^i(e) - \sum_{e \in out(v)} f^i(e) = \sum_{e \in in(v)} f^{i-1}(e) - \sum_{e \in out(v) \setminus \{(v, w)\}} f^{i-1}(e) - f^i(v, w) = excess_{f^{i-1}}(v) - \delta = 0$$

Otherwise if  $(v, w)$  is a backward edge. Then ew flow along  $(w, v)$  is  $f^i(w, v) = f^{i-1}(w, v) - excess_{f^{i-1}}(v)$ . Since  $(w, v) \in in(v)$

$$excess_{f^i}(v) = \sum_{e \in in(v)} f^i(e) - \sum_{e \in out(v)} f^i(e) = f^i(w, v) + \sum_{e \in in(v) \setminus \{(w, v)\}} f^{i-1}(e) - \sum_{e \in out(v)} f^{i-1}(e) = -\delta + excess_{f^{i-1}}(v) = 0$$

In both cases  $excess_{f^i}(v) = 0$ . Therefore  $v$  goes out of the summation. Now there are two cases depending on the value of  $excess_{f^{i-1}}(w)$

- **Case 1:** If  $excess_{f^{i-1}}(w) > 0$  i.e.  $w$  had excess flow before push operation then  $\Phi(f^{i-1})$  decreases by  $l(v)$  i.e.  $\Phi(f^i) = \Phi(f^{i-1}) - l(v)$ . Since  $l(w) = l(v) - 1$  and by [Observation 9.1](#)  $l(v) \geq 1$ . Therefore  $\Phi(f^i) = \Phi(f^{i-1}) - l(v) \leq \Phi(f^{i-1}) - 1$ .
- **Case 2:** If  $excess_{f^{i-1}}(w) = 0$ , then  $excess_{f^i}(w) = excess_{f^{i-1}}(w) + \delta > 0$  since  $\delta = excess_{f^{i-1}}(v) > 0$  and therefore  $\Phi(f^i) = \Phi(f^{i-1}) - l(v) + l(w) = \Phi(f^{i-1}) - 1$

Hence for both the cases  $\Phi(f^i) \leq \Phi(f^{i-1}) - 1$ . Therefore  $\Phi(f^{i-1})$  decreases by at least 1. ■

**Observation 9.4.** For relabeling operation  $\Phi(f)$  increases by 1.

Since there are at most  $2n^2$  relabeling operations by [Corollary 9.3.6](#),  $\Phi(f)$  increases by at most  $2n^2$  with relabeling operations.

**Observation 9.5.** For each saturating push  $excess_f(v, w)$  might not go to 0 and therefore  $\Phi$  might increase.

Now by [Lemma 9.3.7](#) total number of saturated pushes is at most  $2mn$ . And by [Corollary 9.3.5](#) each vertex has label at most  $2n$ . Hence in total  $\Phi(f)$  can increase at most  $2mn \times 2n = 4mn^2$  by saturated pushes. Hence  $\Phi(f)$  increases at most  $2n^2 + 2mn \times 2n = O(mn^2)$ .

Now

$$\# \text{Non-saturating Pushes} \leq \text{Total decrease in } \Phi \leq \text{Total increase in } \Phi \leq 2n^2 + 4mn^2 = O(mn^2)$$

Therefore total number of iterations of the WHILE loop is  $\# \text{Relabeling} + \# \text{Saturated Push} + \# \text{Non-saturated Push} = 2n^2 + 2mn + O(mn^2) = O(mn^2)$ . Therefore the algorithm takes  $O(mn^2)$  iteration. In each iteration it takes  $O(m + n)$  time. Therefore the runtime of the algorithm is  $O(mn^2)O(n + m) = O(m^2n^2)$ .

# Randomized Algorithm

Here we will study randomized algorithm for tow basic problems. Later we will discuss other randomized algorithms too in the next chapters. We will also try to derandomize an algorithm in the next chapter.

## 10.1 Estimated Binary Search Tree Height

In this section we will calculate the expected height of a tree obtained by constructing a binary tree by picking elements uniformly at random from a given array. For this we have the following simple INTERSECTION ALGORITHM

---

**Algorithm 19:** Simple Intersection Algorithm

---

**Input:** Array  $A$  of  $n$  elements of  $[n]$  in any order.

**Output:** Construct a binary tree from  $A$

```

1 begin
2    $S \leftarrow A$ 
3    $T \leftarrow \emptyset$ 
4   while  $S \neq \emptyset$  do
5      $u \leftarrow \text{EXTRACT}(S)$ 
6     Insert each element at the appropriate leaf of  $T$ 
7   return  $T$ 

```

---

### Question 10.1

What is the expected height of the tree obtained by this SIMPLE INTERSECTION ALGORITHM assuming sequence of keys is uniformly random permutation of  $[n]$ .

Suppose  $X_n$  be the random variable for the height of the tree obtained by the algorithm running on any permutation of  $[n]$ . Let  $R_n$  be the random variable for the root of the tree obtained by the algorithm. Now consider the random variable  $Y_n$  defined as  $Y_n = 2^{X_n}$ . Then if we know  $R_n = i$  we have

$$X_n = 1 + \max\{\text{Height of left subtree}, \text{Height of right subtree}\} = 1 + \max\{X_{i-1} + X_{n-i}\} \implies Y_n = 2 \max\{Y_{i-1}, Y_{n-i}\}$$

Now for the case of  $n = 1$   $Y_1 = 1$  since there is only one element and for the convenience we define  $Y_0 = 0$ . Now consider the following indicator random variable  $Z_{n,i}$  where

$$Z_{n,i} = \begin{cases} 1 & \text{if } i \text{ is first element} \\ 0 & \text{otherwise} \end{cases}$$

So basically  $Z_{n,i} = \mathbb{1}\{R_n = i\}$ . Now if  $i$  is the first element then  $i$  the root of the tree obtained by the algorithm. Therefore

we have

$$\begin{aligned}
 Y_n &= \sum_{i=1}^n Z_{n,i} (1 + \max\{Y_{i-1}, Y_{n-i}\}) \\
 &\leq 2 \sum_{i=1}^n Z_{n,i} (Y_{i-1} + Y_{n-i}) \quad [\text{Using Lemma 10.1.1}]
 \end{aligned}$$

**Lemma 10.1.1 Soft Max**

For any  $a, b \in \mathbb{R}$ ,

$$\max\{a, b\} \leq \log(2^a + 2^b)$$

Therefore we have

$$\begin{aligned}
 \mathbb{E}[Y_n] &\leq 2 \sum_{i=1}^n \mathbb{E}[Z_{n,i} (Y_{i-1} + Y_{n-i})] \\
 &= 2 \sum_{i=1}^n \mathbb{E}[Z_{n,i}] \mathbb{E}[Y_{i-1} + Y_{n-i}] \\
 &= \frac{2}{n} \sum_{i=1}^n (\mathbb{E}[Y_{i-1}] + \mathbb{E}[Y_{n-i}]) = \frac{4}{n} \sum_{i=0}^{n-1} \mathbb{E}[Y_i]
 \end{aligned}$$

Now to compute  $\mathbb{E}[Y_n]$  we use the following lemma

**Lemma 10.1.2**

$$\mathbb{E}[Y_n] \leq \frac{1}{4} \binom{n+3}{3}$$

**Proof:** We will prove this using induction on  $n$ . The base case is true for  $n = 0$ . Suppose this is true for  $0, \dots, n-1$ .

$$\mathbb{E}[Y_n] \leq \frac{4}{n} \sum_{i=0}^{n-1} \mathbb{E}[Y_i] \leq \frac{1}{n} \sum_{i=0}^{n-1} \binom{i+3}{3} = \frac{1}{n} \binom{n+3}{4} = \frac{1}{n} \frac{(n+3)!}{4!(n-1)!} = \frac{1}{4} \binom{n+3}{3}$$

Hence by mathematical induction this is true for all  $n$ . ■

Hence by the lemma we have  $\mathbb{E}[Y_n] \leq \frac{1}{4} \binom{n+3}{3} = O(n^3)$ . Now by Jensen Inequality we have

$$\mathbb{E}[Y_n] = \mathbb{E}[2^{X_n}] \geq 2^{\mathbb{E}[X_n]}$$

Therefore  $\mathbb{E}[X_n] \leq O(\log n)$ . Therefore the expected height of a binary search tree is  $O(\log n)$ .

## 10.2 Solving 2-SAT

In this section we will discuss a randomized algorithm for deciding if a  $n$ -variate 2-SAT boolean formula is satisfiable or not.

2-SAT

**Input:** 2-SAT formula  $\varphi$  consisting of  $n$  variables.

**Question:** Given  $n$ -variate 2-SAT boolean formula determine if  $\varphi$  is satisfiable.

Here we give a simple randomized algorithm for solving the 2-SAT problem:

**Algorithm 20:** 2-SAT Randomized Algorithm

---

**Input:**  $n$  variate 2-SAT formula  $\varphi$   
**Output:** Decide if  $\varphi$  is satisfiable or not

```

1 begin
2    $\forall i \in [n]$ , Set  $x_i = 0$ 
3   while  $\exists$  clause  $C$  that is not satisfied do
4     Let  $x_i$  and  $x_j$  be variables in  $C$ 
5     Pick from  $\{x_i, x_j\}$  with equal probability and flip the assignment for that variable.
6   return  $x$ 

```

---

Now if the algorithm terminates it terminates with a satisfying assignment. For now assume that  $\varphi$  is satisfiable. We will deal with the case that  $\varphi$  is not satisfiable later.

Now since there are  $n$  variables there can be at most  $O(n^2)$  many clauses can be in the formula. Therefore for each step of the while loop to occur it can at most take  $O(n^2)$  time to find a clause which is not satisfied.

Let  $S$  represents the set of satisfying assignments for  $\varphi$ . Let at  $j^{th}$  iteration let  $A_j$  denote the current assignment of the variables. Let  $X_j$  be the random variable which denotes maximum number of variables of  $A_j$  that matches with some satisfying assignment of  $S$  i.e.

$$X_j = \max\{n - |x - A_j| : x \in S\}$$

At any step if  $X_j = n$  then the algorithm terminates since the algorithm has found a satisfying assignment. Now starting with  $X_j < n$  we consider how  $X_j$  evolves over time and how long it takes before  $X_j$  reaches  $n$ .

Now at each step we pick a clause which is unsatisfied. So we know  $A_j$  and all assignments of  $S$  disagree on the value of at least one variable of this clause. If all the assignments in  $S$  disagree with  $A_j$  on both variables changing either one will increase  $X_j$ . If there are assignments in  $S$  which disagree on the value of one of the two variables then with probability  $\frac{1}{2}$  we choose that variable and increase  $X_j$  by 1 and with probability  $\frac{1}{2}$  we choose the other variable and decrease  $X_j$  by 1.

Therefore  $X_j$  behaves like a random walk on a line starting from 0 which denotes the worst possible case and ends once it reaches at  $n$  where at any nonzero point it goes up or down by 1 with probability  $\frac{1}{2}$ . This is a Markov Chain. We want to calculate how many steps does it take on average for  $X_j$  to stumble all the way up to  $n$ . Before that we first properly define our Markov Chain.

The Markov Chain consists states from 0 to  $n$ . Where from 0 it goes to 1 with probability 1 and from  $n$  it always stays at  $n$ . And for any other state  $i$  it goes to  $i + 1$  with probability  $\frac{1}{2}$  and goes to  $i - 1$  with probability  $\frac{1}{2}$ . Now let

$$T(k) = \text{Expected time to walk from } k \text{ to } n$$

Then we have

$$T(n) = 0, \quad T(0) = T(1) + 1, \quad \forall i \in [n - 1], \quad T(i) = \frac{T(i - 1)}{2} + \frac{T(i + 1)}{2} + 1$$

Then we have  $n$  unknowns and  $n$  equations in the above system. Therefore on average at most  $O(n^2)$  steps needed to find a solution.

Now at first we said we are assuming we are dealing with the case of there exists a solution.

**Question 10.2**

How to deal with the issue of no solution?

In this case we will run for more number of iterations before we give up since when we give up we might just not have found the solution. So we will run the algorithm for  $100n^2$  steps. And if no solution was found then we will give up.

We first of all divide the execution of the algorithm into segments of  $2n^2$  steps each. We will calculate the failure case of each segment. If the 2-SAT formula has no solution then the algorithm gives correct output. Suppose it has a solution. Then by Markov's Inequality the probability of number of steps needed to find the solution is greater than the expected number of steps needed to find a solution is at most  $\frac{1}{2}$ . Now after total  $100n^2$  steps the probability none of the segments found a solution is  $2^{-50}$ .

# Derandomization

In this section we will see a derandomization technique called Conditional Expectation. With this technique we will show derandomization of some randomized algorithms in the following sections.

## 11.1 Conditional Expectation

Let  $\mathcal{A}$  be a randomized algorithm which is successful with probability at least  $\frac{2}{3}$ . Suppose  $\mathcal{A}$  uses  $m$  random bits and suppose the random bits are  $R_1, \dots, R_m$ . Then we have

$$\mathbb{P}_{R_1, \dots, R_m} [\mathcal{A}(x, R_1, \dots, R_m) = \text{Correct}] \geq \frac{2}{3}$$

We want to derandomize  $\mathcal{A}$ .

Now think of  $\mathcal{A}$  as a binary tree which, given  $x$ , branches on the sampled value of each random bit  $R_i$  where it goes to left child if the random bit takes value 0 and goes to right child if the random bit takes value 1. Every path in this tree from root to leaf corresponds to different possible random strings and the leaf nodes corresponds to the output of the algorithm with the corresponding random string. Since  $\mathcal{A}$  succeeds with probability at least  $\frac{2}{3}$  means that at least  $\frac{2}{3}$  of the leaves are good outputs for the input  $x$ .

**Idea.** To derandomize  $\mathcal{A}$  we need to find a deterministic algorithm that traverses from the root to a leaf which at any branch at level  $i$  chooses a direction which leads to a good output.

Now suppose  $r_1, \dots, r_m \in \{0, 1\}$  denote the values taken by the random variables  $R_1, \dots, R_m$ . Now let  $P(r_1, \dots, r_i)$  denote the fraction of the leaves of the subtree below the node obtained by following the path  $r_1, \dots, r_i$ . Formally,

$$P(r_1, \dots, r_i) = \mathbb{P}[\mathcal{A}(x, R_1, \dots, R_m) \mid R_1 = r_1, \dots, R_i = r_i] = \frac{1}{2}P(r_1, \dots, r_i, 0) + \frac{1}{2}P(r_1, \dots, r_i, 1)$$

From the last equality it is clear that there is a choice  $r_{i+1}$  such that  $P(r_1, \dots, r_{i+1}) \geq P(r_1, \dots, r_i)$ . Therefore to find a good path in the tree it suffices at each branch to pick such an  $r \in \{0, 1\}$ . Then we would have

$$P(r_1, \dots, r_m) \geq P(r_1, \dots, r_{m-1}) \geq \dots \geq P(r_1) \geq \mathbb{P}[\mathcal{A}(x, R_1, \dots, R_m) = \text{Correct}] \geq \frac{2}{3}$$

Since  $P(r_1, \dots, r_m)$  is either 0 or 1 it must be 1.

## 11.2 MAX-SAT

MAX-SAT

**Input:** SAT formula  $\varphi$  with  $n$  variables and  $m$  clauses and non negative weights  $w_c$  on clauses.

**Question:** Given a SAT formula  $\varphi$  with  $n$  variables and  $m$  clauses and non negative weights  $w_c$  on clauses find an assignment that maximizes weight of satisfied clauses.

We will first show a randomized algorithm for this problem. Then we will use conditional expectation to derandomize the algorithm.

### 11.2.1 Randomized Algorithm

First lets see what is the expected weight of satisfied clauses. Let  $Y_c$  be the indicator random variable if clause  $C$  is satisfied. Suppose there are  $k$  variables in  $C$ . Then we have  $\mathbb{E}[Y_c] = 1 - \frac{1}{2^k} \geq \frac{1}{2}$ . Therefore expected weight of satisfied clauses is

$$\mathbb{E} \left[ \sum_C w_c Y_c \right] = \sum_C w_c \mathbb{E}[Y_c] \geq \frac{1}{2} \sum_C w_c$$

Let OPT be the optimal MAX-SAT solution for the given formula. Then we have  $\sum_C w_c \geq \text{OPT}$ . Therefore

$$\mathbb{E} \left[ \sum_C w_c Y_c \right] \geq \frac{1}{2} \text{OPT}$$

Hence we have the following randomized algorithm:

---

**Algorithm 21:** 2-APPROXIMATE MAX-SAT

---

**Input:** SAT formula  $\varphi$  with  $n$  variables and  $m$  clauses and non negative weights  $w_c$  on clauses.

**Output:** Find an assignment that maximizes weight of satisfied clauses.

```

1 begin
2   for  $i \in [n]$  do
3      $x_i \leftarrow$  Pick a value from  $\{0, 1\}$  uniformly at random
4   return  $x$ 

```

---

By the above discussion we have an assignment with an expected weight of satisfied clauses at least half the maximum.

### 11.2.2 Derandomization

Now we want to derandomize the algorithm using conditional expectation. Let  $X_1, \dots, X_n$  denote the random variable for each variables and  $x_1, \dots, x_n \in \{0, 1\}$  denote the value the random variables took. A key step will be evaluate the conditional probabilities:

$$\mathbb{E} \left[ \sum_C w_c Y_c \mid X_1 = x_1, \dots, X_i = x_i \right] = \sum_C w_c \mathbb{P}[Y_c = 1 \mid X_1 = x_1, \dots, X_i = x_i] \quad \forall i \in [n]$$

Hence we have to find the value of  $\mathbb{P}[Y_c = 1 \mid X_1 = x_1, \dots, X_i = x_i]$ ,  $\forall i \in [n]$ . Now if the clause  $C$  is already satisfied by the setting  $x_1, \dots, x_i$  then  $Y_c = 1$ . Else if  $C$  has  $r$  variables from  $x_{i+1}, \dots, x_n$  then

$$\mathbb{P}[Y_c = 1 \mid X_1 = x_1, \dots, X_i = x_i] = 1 - \frac{1}{2^r}$$

. Now if at height  $i$ , we find  $\mathbb{E} [\sum_C w_c Y_c \mid X_1 = x_1, \dots, X_i = 0]$  and  $\mathbb{E} [\sum_C w_c Y_c \mid X_1 = x_1, \dots, X_i = 1]$  and which ever gives the higher value we will set the assignment for  $X_i$  to be that one. Thus we can derandomize the algorithm.

## 11.3 Set Balancing

SET-BALANCE

**Input:**  $A \in \{0, 1\}^{n \times n}$  matrix with  $A_i$  is the  $i^{th}$  row of  $A$  and  $A_{i,j}$  is the  $(i, j)^{th}$  entry

**Question:** Given  $n \times n$ , 0-1 matrix  $A$  find  $b \in \{1, -1\}^n$  to minimize  $\|Ab\|_\infty = \max_{i \in [n]} |A_i b|$ .

In the following sections we will not optimize on  $\|Ab\|_\infty$ . Instead we will give bound on how large  $\min \|Ab\|_\infty$  can be for any  $A$ .

**Algorithm 22:** SET-BALANCING

---

**Input:**  $A \in \{0, 1\}^{n \times n}$  matrix  
**Output:** Find an  $b \in \{1, -1\}^n$  to minimize  $\|Ab\|_\infty$

```

1 begin
2   for  $i \in [n]$  do
3      $x_i \leftarrow$  Pick a value from  $\{1, -1\}$  uniformly at random
4   return  $x$ 

```

---

**11.3.1 Randomized Algorithm**

Clearly for each row  $i \in [n]$  we have

$$\mathbb{E}[A_i b] = \mathbb{E}\left[\sum_j A_{i,j} b_j\right] = \sum_j \mathbb{E}[A_{i,j} b_j] = 0$$

But that does not mean  $\mathbb{E}[|A_i b|] = 0$ . To get a bound on  $\mathbb{E}[|A_i b|]$  we will use Hoeffding's Inequality

**Theorem 11.3.1** Hoeffding's Inequality

Let  $Y_1, \dots, Y_n$  be independent random variables with bounded support  $[l_i, u_i]$  for  $Y_i$  and let  $Y = \sum_{i=1}^n Y_i$ . Then for any  $\delta > 0$

$$\mathbb{P}[|Y - \mathbb{E}[Y]| > \delta] \leq 2e^{-\frac{2\delta^2}{\sum_i (u_i - l_i)^2}}$$

In our case we have  $Y_{i,j} = A_{i,j} b_j$  and  $Y_i = \sum_j A_{i,j} b_j$ . Then each  $Y_{i,j} \in \{-1, 0, 1\}$ ,  $\mathbb{E}[Y_{i,j}] = 0$  and  $\mathbb{E}[Y_i] = 0$ .

Therefore

$$\mathbb{P}[|Y_i| > \delta] \leq 2e^{-\frac{2\delta^2}{4n}}$$

Now we choose  $\delta = 2\sqrt{n \ln n}$

$$\mathbb{P}[|A_i b| \geq 2\sqrt{n \ln n}] \leq \frac{2}{n^2}$$

Therefore  $\mathbb{P}[\|Ab\|_\infty \geq 2\sqrt{n \ln n}] \leq \frac{2}{n}$  by union bound. Hence choosing each entry  $b$  uniformly at random from  $\pm 1$  we can obtain  $\|Ab\|_\infty \leq 2\sqrt{n \ln n}$  with high probability.

**11.3.2 Derandomization**

Again we will use conditional expectation to derandomize the algorithm. Let a node at height  $j$  corresponds to a setting of  $b_1, \dots, b_j$  and we will calculate  $\mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_j]$ . Now consider a leaf corresponding to some choice of  $b_1, \dots, b_n$  such that the value of the leaf is  $< 1$ . But there is no randomness at the leaf. Then  $\mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_n] = 0$ . Hence for this choice of  $b_1, \dots, b_n$  it must have  $\|Ab\|_\infty \leq 2\sqrt{n \ln n}$ . Now

$$\mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_j] = \mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_j, 0] + \mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_j, 1]$$

One of them have

$$\mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_j, b_{j+1}] \leq \mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n} \mid b_1, \dots, b_j]$$

So we choose that one. Also note that at the root  $\mathbb{P}[\|Ab\|_\infty > 2\sqrt{n \ln n}] < \frac{2}{n}$ . Then for choosing such a path for the corresponding choice of  $b$  we will have  $\|Ab\|_\infty \leq M = 2\sqrt{n \ln n}$ . But this depends on being able to calculate  $\mathbb{P}[\|Ab\|_\infty > M \mid b_1, \dots, b_j]$  which we don't know how to do in polynomial time. Instead we will use pessimistic estimator which.

### 11.3.3 Using Pessimistic Estimator to Derandomize

Instead of  $\mathbb{P}[\|Ab\|_\infty > M \mid b_1, \dots, b_j]$  we will use  $\sum_{i \in [n]} \mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j]$ . Naturally we have

$$\sum_{i \in [n]} \mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j] \geq \mathbb{P}[\|Ab\|_\infty > M \mid b_1, \dots, b_j]$$

Now we know how to calculate  $\mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j]$ . For any  $i \in [n]$  we have

$$\mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j] = \sum_{k=M+1}^n \mathbb{P}[A_i b = k \mid b_1, \dots, b_j] + \mathbb{P}[A_i b = -k \mid b_1, \dots, b_j]$$

Let  $S_i = \{j' > j : A_{i,j'} = 1\}$  and  $l = \sum_{j' \leq j} A_{i,j'}$ . Then

$$\mathbb{P}[A_i b = k \mid b_1, \dots, b_j] = \mathbb{P}\left[\sum_{j' \in S_i} b_{j'} = k - l\right]$$

Let in  $S_i$   $n_i$  coordinates of  $b$  are 1 and rest of the coordinates of  $b$  in  $S_i$  are  $-1$ . Then

$$\sum_{j' \in S_i} b_{j'} = 2n_i - |S_i| = k - l \implies n_i = \frac{1}{2}(k - l + |S_i|)$$

Therefore we have

$$\mathbb{P}[A_i b = k \mid b_1, \dots, b_j] = \frac{1}{2^{|S_i|}} \binom{|S_i|}{\frac{1}{2}(k - l + |S_i|)}$$

Thus we can calculate  $\mathbb{P}[A_i b = k \mid b_1, \dots, b_j]$  for all  $n \geq |k| > M$ . Therefore we can calculate  $\mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j]$  and henceforth  $\sum_{i \in [n]} \mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j]$ . With this pessimistic estimator we calculate at height  $j$  both  $\sum_{i \in [n]} \mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j, b_{j+1} = 0]$  and  $\sum_{i \in [n]} \mathbb{P}[|A_i b| > M \mid b_1, \dots, b_j, b_{j+1} = 1]$  and the one which have value less than 1 we will follow that path and eventually we will get an assignment of  $b$  for which  $\|Ab\|_\infty \leq 2\sqrt{n \ln n}$ .

# CHAPTER 12

## Global Min Cut

# CHAPTER 13

## Matching

In [section 5.1](#) we saw how to find a maximal matching in a graph using matroids. Here we will try to find maximum matching.

MAXIMUM MATCHING

**Input:** Graph  $G = (V, E)$

**Question:** Find a maximum matching  $M \subseteq E$  of  $G$

First we will solve finding maximum matching in bipartite graphs first. Then we will extend the algorithm to general graphs.

### 13.1 Bipartite Matching

So in this section we will study the following problem:

BIPARTITE MAXIMUM MATCHING

**Input:** Graph  $G = (L \cup R, E)$

**Question:** Find a maximum matching  $M \subseteq E$  of  $G$

#### 13.1.1 Using Max Flow

One approach to find a maximum matching is by using [max-flow algorithm](#). For this we introduce 2 new vertices  $s$  and  $t$  where there is an edge from  $s$  to every vertex in  $L$  and there is an edge from every vertex in  $R$  to  $t$  and all edges have capacity 1. Then the max-flow for this directed graph is the maximum matching of the bipartite graph. So we have the algorithm:

---

**Algorithm 23:** BP-MAX-MATCHING-FLOW

---

**Input:**  $G = (L \cup R, E)$  bipartite graph  
**Output:** Find a maximum matching

```
1 begin
2    $V \leftarrow A \cup B \cup \{s, t\}$ 
3    $E' \leftarrow E$ 
4   for  $v \in L$  do
5      $E' \leftarrow E' \cup \{(s, v)\}$ 
6   for  $v \in R$  do
7      $E' \leftarrow E' \cup \{(v, t)\}$ 
8   for  $e \in E'$  do
9      $c_e \leftarrow 1$ 
10   $f \leftarrow \text{EDMONDS-KARP}(G' = (V, E'), \{c_e : e \in E'\})$ 
11  return  $\{e : f(e) > 0, e \in E\}$ 
```

---

**Lemma 13.1.1**

There exists a max-flow of value  $k$  in the modified graph  $G' = (V, E')$  if and only there is a matching of size  $k$

**Proof:** Suppose  $G'$  has a matching  $M$  of size  $k$ . Let  $M = \{(u_i, v_i) : i \in [k]\}$  where  $u_i \in L$  and  $v_i \in R$  for all  $i \in [k]$ . Then we have the flow  $f$ ,  $f(s, u_i) = f(u_i, v_i) = f(v_i, t) = 1$  for all  $i \in [k]$ . This flow has value  $k$ .

Now suppose there is a flow  $f$  of value  $k$ . Since each edge has capacity 1 then either an edge has flow 1 or it has 0 flow. Since value of flow is  $k$  there are exactly  $k$  edges outgoing from  $s$  with positive flow. Let the edges are  $(s, u_i)$  for  $i \in [k]$ . Now from each  $u_i$  there is exactly one edge going out which has positive flow. Now if  $\exists i \neq j \in [k]$  such that  $\exists v \in R$ ,  $f(u_i, v) = f(u_j, v) = 1$  then  $f(v, t) = 2$  but  $c_{v,t} = 1$ . So this is not possible. Therefore the edges going out from each  $u_i$  goes to distinct vertices. These edges now form a matching of size  $k$ . ■

Therefore the algorithm successfully returns a maximum matching of the bipertite graph. But we don't know any algorithm for finding maximum matching in general graphs using max-flow. In the next algorithm we will use something called Augmenting paths to find a maximum matching which we will extend to general graphs.

### 13.1.2 Using Augmenting Paths

#### Definition 13.1.1: $M$ -Alternating Path and Augmenting Path

In a graph  $G = (V, E)$  and  $M$  be a matching in  $G$ . Then an  $M$ -alternating path is where the edges from  $M$  and  $E \setminus M$  appear alternatively.

An  $M$ -alternating path between two unmatched (also called exposed) vertices is called an augmenting path.

Given a matching  $M$  and if there exists an augmenting path  $p$  then we can obtain a larger matching  $M'$  just by taking the edges in  $p$  not in  $M$ . Now suppose we are given a bipartite graph  $G = (L \cup R, E)$ . Let  $M$  is a matching in  $G$ . Suppose  $M$  is a maximum matching. If there exists an augmenting path  $p$  then we can obtain a larger matching just by taking the edges in  $p$  not in  $M$ . This contradicts with  $M$  is maximum matching. Hence there are no augmenting paths.

Now we will show that given  $G$  and  $M$  which is not maximum then we can find an augmenting path with an algorithm. Since  $M$  is not maximum there is a vertex  $v$  which is not matched

---

#### Algorithm 24: FIND-AUGMENTING-PATH( $G, v$ )

---

**Input:**  $G = (L \cup R, E)$  bipartite graph, matching  $M$  (not maximum) and an exposed vertex  $v$

**Output:** Find an augmenting path starting from  $v$

```

1 begin
2    $v.mark \leftarrow \text{even}$ 
3   for  $u \in L \cup R \setminus \{v\}$  do
4      $u.mark \leftarrow \text{NULL}$ 
5    $QUEUE\ Q$  // For BFS
6    $ENQUEUE(Q, v)$ 
7   while  $Q$  not empty do
8      $AUTREE(Q)$ 
9   return FAIL

```

---

---

#### Algorithm 25: AUTREE( $Q$ )

---

```

1  $u \leftarrow DEQUEUE(Q)$ 
2 if  $u.mark == \text{even}$  then
3   for  $(u, w) \in E \setminus M$  do
4     if  $w.mark == \text{NULL}$  then
5        $ENQUEUE(Q, w)$ 
6        $w.mark \leftarrow \text{odd}$ 
7        $w.p \leftarrow u$ 
8 if  $u.mark == \text{odd}$  then
9   if  $\exists (u, w) \in M$  and  $w.mark == \text{NULL}$  then
10     $w.mark \leftarrow \text{even}$ 
11     $w.p \leftarrow u$ 
12     $ENQUEUE(Q, w)$ 
13 else
14   Print " $v \rightsquigarrow u$  augmenting path found"

```

---

**Lemma 13.1.4**

Suppose we start the algorithm from an exposed vertex  $v$ . Suppose there is no augmenting path from  $v$  and let the tree formed by the algorithm is  $T$ . Then  $|L_T| = |R_T| + 1$ .

**Proof:** Since there is no augmenting path the graph all the leaves of  $T$  are even vertices. Otherwise the leaves are odd vertices and then all of them have to be matched. If not then there will exist an augmenting path. Therefore all the leaves of  $T$  are even vertices. Now since the vertices in  $L_T$  are even vertices and all even vertices except  $v$  are matched to unique odd vertex in  $R_T$  we have  $|L_T| = |R_T| + 1$ . ■

Now suppose  $M$  is a matching. Let  $L' = \{v_1, \dots, v_k\} \subseteq L$  are unmatched vertices. Therefore  $|M| = |L| - k$ . Then consider the following algorithm:

- Let  $T_1$  be  $M$ -alternating tree from  $v_1$  by FIND-AUGMENTING-PATH( $G, v_1$ ).  $L_{T_1}, R_{T_1}$  are vertices of  $T_1$ .
- Let  $T_2$  be  $M$ -alternating tree from  $v_2$  by FIND-AUGMENTING-PATH( $G \setminus T_1, v_2$ ).  $L_{T_2}, R_{T_2}$  are vertices of  $T_2$ .
- Let  $T_3$  be  $M$ -alternating tree from  $v_3$  by FIND-AUGMENTING-PATH( $G \setminus (T_1 \cup T_2), v_3$ ).  $L_{T_3}, R_{T_3}$  are vertices of  $T_3$ .  $\dots$
- Let  $T_k$  be  $M$ -alternating tree from  $v_k$  by FIND-AUGMENTING-PATH( $G \setminus \left(\bigcup_{i=1}^{k-1} T_i\right), v_k$ ).  $L_{T_k}, R_{T_k}$  are vertices of  $T_k$ .

**Observation 13.4.**  $v_i$  is not in  $T_j$  for any  $j < i$  because otherwise we would have found an augmenting path in  $T_j$ .

Now  $L_{T_i}$  for all  $i \in [k]$  are disjoint and  $R_{T_i}$  for all  $i \in [k]$  are disjoint. If  $G$  had no augmenting path from  $v_i$  for all  $i \in [k]$  then there are no augmenting paths in  $G \setminus \left(\bigcup_{i=1}^j T_i\right)$  for all  $j \in [k-1]$  from  $v_{j+1}$ . Therefore by Lemma 13.1.4 we have  $|L_{T_i}| = |R_{T_i}| + 1 \forall i \in [k]$ . Hence we have

$$\sum_{i=1}^k |L_{T_i}| = \sum_{i=1}^k (|R_{T_i}| + 1) \implies \left| \bigcup_{i=1}^k L_{T_i} \right| = \left| \bigcup_{i=1}^k R_{T_i} \right| + k$$

Now by Lemma 13.1.3,  $N(L_{T_{j+1}}) = R_{T_{j+1}}$  for all  $j \in [k-1]$  in  $G \setminus \left(\bigcup_{i=1}^j T_i\right)$ . Hence

$$N(L_{T_j}) \subseteq \bigcup_{i=1}^j R_{T_i} \implies N\left(\bigcup_{i=1}^k L_{T_i}\right) = \bigcup_{i=1}^k R_{T_i}$$

But  $\left| \bigcup_{i=1}^k L_{T_i} \right| = \left| \bigcup_{i=1}^k R_{T_i} \right| + k$ . Therefore any matching of  $\bigcup_{i=1}^k L_{T_i}$  must leave at least  $k$  vertices unmatched. Now all the vertices in  $L \setminus \left(\bigcup_{i=1}^k L_{T_i}\right)$  with  $R \setminus \left(\bigcup_{i=1}^k R_{T_i}\right)$  and vice versa. Therefore any matching of  $L$  must leave at least  $k$  vertices unmatched. Since  $M$  is a matching such that exactly  $k$  vertices are unmatched.  $M$  is a maximum matching. Therefore if there is no augmenting path in  $G$  then  $M$  is a maximum matching.

We also showed before that if  $M$  is a maximum matching then there is no augmenting path in  $G$ . Therefore we have the following theorem:

**Theorem 13.1.5 Berge's Theorem**

A matching  $M$  is maximum if and only if there are no augmenting path in  $G$ .

Therefore if we start with any matching and each time we find an augmenting path we update the matching by taking the odd edges in the augmenting path and obtain a larger matching. After continuously doing this once when there is no augmenting path we can conclude that we obtained a maximum matching.

Since every time the size of the maximal matching is increased by at least 1. The total number of iterations the algorithm takes to output the maximal matching is  $O(n)$  where  $n$  is the number of vertices in  $G$ . In each iteration it calls the FIND-AUGMENTING-PATH algorithm which takes the time same as time taken in BFS. Hence FIND-AUGMENTING-PATH takes  $O(m + n)$  time. Therefore the BP-MAXIMUM-MATCHING algorithm takes  $O(n(n + m))$  time.

**Algorithm 26:** BP-MAXIMUM-MATCHING( $G$ )

---

**Input:**  $G = (L \cup R, E)$  bipartite graph  
**Output:** Find a maximum matching

```

1 begin
2    $M \leftarrow \emptyset$ 
3   while True do
4      $v \leftarrow$  unmatched vertex
5      $p \leftarrow$  FIND-AUGMENTING-PATH
6     if  $p == \text{FAIL}$  then
7       return  $M$ 
8     for  $e \in p$  do
9       if  $e \in M$  then
10         $M \leftarrow M \setminus \{e\}$ 
11       else
12         $M \leftarrow M \cup \{e\}$ 

```

**13.1.3 Using Matrix Scaling**

Here we will show a new algorithm for deciding if a bipartite graph has a perfect matching using matrix scaling. The paper which we will follow is [LSW98]

**BIPARTITE PERFECT MATCHING**

**Input:** Graph  $G = (L \cup R, E)$

**Question:** Decide if  $G$  has a perfect matching or not.

Suppose  $G = (L \cup R, E)$  a bipartite graph. If bipartite adjacency matrix of the graph  $G$  is  $A$  then the permanent of the matrix  $A$ ,

$$\text{per}(A) = \sum_{\sigma \in S_n} \prod_{i=1}^n x_{i, \sigma(i)}$$

counts the number of perfect matchings in  $G$ . So we want to check if for a given bipartite graph  $(L \cup R, E)$ ,  $\text{per}(A) > 0$  or not where  $A$  is the bipartite adjacency matrix. Now there is a necessary and sufficient condition for existence of perfect matching in a bipartite graph which is called Hall's condition.

**Theorem 13.1.6 Hall's Condition**

A bipartite graph  $G = (L \cup R, E)$  has an  $L$ -perfect matching if and only if  $\forall S \subseteq L, |S| \leq |N(S)|$  where  $N(S) = \{v \in R : \exists u \in L, (u, v) \in E\}$

**Proof:** Now if  $G$  has a  $L$ -perfect matching then for every  $S \subseteq L$ ,  $S$  is matched with some  $T \subseteq R$  such that  $|S| = |T|$ . Therefore  $T \subseteq N(S) \implies |S| = |T| \leq |N(S)|$ .

Now we will prove the opposite direction. Suppose for all  $S \subseteq L$  we have  $|S| \leq |N(S)|$ . Assume there is no  $L$ -perfect matching in  $G$ . Let  $M$  be a maximum  $L$ -matching in  $G$ . Let  $u \in L$  is unmatched. Now consider the following sets:

$$X = \{x \in L : \exists M\text{-alternating path from } u \text{ to } x\}, \quad Y = \{y \in R : \exists M\text{-alternating path from } u \text{ to } y\}$$

Now notice that  $N(X) \subseteq Y$ . Since in a  $M$ -alternating path from  $u$  whenever the odd edges are not matching edges and the even edges are matching edges. So in the odd edges we can pick any neighbor except the one it is matched with and the immediate even edge before that connects that vertex with the vertex in  $R$  it is matched with. Hence we have  $N(X) \subseteq Y$ .

Now it suffices to prove that  $|X| > |Y|$ . Now let  $y \in Y$ . Suppose  $u \rightsquigarrow x' \rightarrow y$  be the  $M$ -alternating path. If  $y$  is not matched then we could increase the matching by taking the odd edges of the path and thus obtain a matching with larger size than  $M$ . But  $M$  is maximum matching. Hence  $y$  is matched. Therefore we can extend the path by taking the matching edge incident on  $y$  and go to the vertex  $x'' \in L$  i.e. the new  $M$ -alternating path becomes  $u \rightsquigarrow x' \rightarrow y \rightarrow x''$  to have a  $M$ -alternating path  $u \rightsquigarrow x''$ . So  $|X| > |Y|$ .

Therefore we obtained a set of vertices  $X \subseteq Y$  such that  $|X| > |Y| \geq |N(X)|$ . This contradicts the assumption. Hence contradiction. Therefore  $G$  has a  $L$ -perfect matching. ■

We will use hall's condition on the adjacency matrix to check if  $\text{per}(A)$  is positive or not. Now multiplying a row or a column of a matrix by some constant  $c$  also multiplies the permanent of the matrix by  $c$  as well. In fact if  $d_1, d_2 \in \mathbb{R}_+^n$  and  $D_1 = \text{diag}(d_1)$  and  $D_2 = \text{diag}(d_2)$  then  $\text{per}(D_1 A D_2) = \left( \prod_{i=1}^n d_{1_i} \right) \left( \prod_{i=1}^n d_{2_i} \right) \text{per}(A)$ . So we can scale our original matrix  $A$  to obtain a different matrix  $B$  and from  $B$  we can approximate  $\text{per}(A)$  by approximating  $\text{per}(B)$ . A natural strategy is to seek an efficient algorithm for scaling  $A$  to a doubly stochastic  $B$ .

### Definition 13.1.2: Doubly Stochastic Matrix

A matrix  $M \in \mathbb{R}^{m \times m}$  is doubly stochastic if entries are non-negative and each row and column sum to 1.

First we will show that Hall's Condition holds for doubly stochastic matrix. First let's see what it means for a matrix to satisfy hall's condition. A matrix with all entries non-negative holds Hall's Condition if for all  $S \subseteq [n]$  if  $T = \{i \in [n] : \exists j \in S, A(i, j) \neq 0\}$  then  $|T| \geq |S|$ . This also corresponds to the bipartite adjacency matrix satisfying the hall's condition since for any set of rows  $S$  the number of columns for which in the  $S$  rows at least one entry is non zero should be greater than or equal to  $|S|$ .

### Lemma 13.1.7

Hall's Condition holds for doubly stochastic matrix.

**Proof:** Let  $M$  be the doubly stochastic matrix. Let  $S \subseteq [n]$ . So consider the  $|S| \times n$  matrix which only consists of the rows in  $S$ . Call this matrix  $M_S^r$ . Now suppose  $T$  be the set of columns in  $M_S^r$  which has nonzero entries. Now consider the  $n \times |T|$  matrix which only consists of the columns in  $T$ . Call this matrix  $M_T^c$ . Now since  $M$  is doubly stochastic we know sum of entries of  $M_S^r$  is  $|S|$  and sum of entries of  $M_T^c$  is  $|T|$ . Our goal is to show  $|S| \leq |T|$ . Now since  $T$  is the only set of columns which have nonzero columns in  $M_S^r$  the elements which contributes to the sum of entries in  $M_S^r$  are in the  $T$  columns in  $M_S^r$ . Since these elements are also present in  $M_T^c$  we have  $|T| \geq |S|$ . ■

Hence for doubly stochastic matrices the permanent is positive. Now not all matrices are doubly stochastic. And in fact matrices with permanent zero will not be doubly stochastic so no amount of scaling will make it doubly stochastic. So we will settle for approximately doubly stochastic matrix. In order to make a matrix doubly stochastic first for each row we will divide the row with their row sum. Now it becomes row stochastic. Then if its not approximately doubly stochastic for each column we will divide the column entries with their column sum. But first what  $\epsilon$ -approximate doubly stochastic matrix means.

### Definition 13.1.3: $\epsilon$ -Approximate Doubly Stochastic Matrix

A matrix is  $\epsilon$ -approximate doubly stochastic if for each column, the column sum is in  $(1 - \epsilon, 1 + \epsilon)$  and for each row, the row sum is in  $(1 - \epsilon, 1 + \epsilon)$

Now we will show that even for  $\epsilon$ -approximate doubly stochastic matrix the hall's condition holds.

### Lemma 13.1.8

Halls's Condition holds for  $\epsilon$ -approximate doubly stochastic matrix for  $\epsilon < \frac{1}{10n}$

**Proof:** Let  $M$  is  $\epsilon$ -approximate doubly stochastic matrix. Let  $S \subseteq [n]$ . So consider the  $|S| \times n$  matrix which only consists of the rows in  $S$ . Call this matrix  $M_S^r$ . Now suppose  $T$  be the set of columns in  $M_S^r$  which has nonzero entries. Now consider the  $n \times |T|$  matrix which only consists of the columns in  $T$ . Call this matrix  $M_T^c$ . Now the sum of entries in  $M_S^r$  is  $\geq |S|(1 - \epsilon)$  and sum of entries in  $M_T^c$  is  $\leq |T|(1 + \epsilon)$ . Now since  $T$  is the only set of columns which have nonzero columns in  $M_S^r$  the elements which contributes to the sum of entries in  $M_S^r$  are in the  $T$  columns in  $M_S^r$ . Since these elements are also present in  $M_T^c$  we have  $|T|(1 + \epsilon) \geq |S|(1 - \epsilon)$ . Therefore we have

$$|T| \geq |S| \frac{1 - \epsilon}{1 + \epsilon} = |S| \left( 1 - \frac{2\epsilon}{1 + \epsilon} \right) \geq |S|(1 - 2\epsilon) > |S| \left( 1 - \frac{1}{5n} \right) \geq |S| \left( 1 - \frac{1}{|S|} \right) > |S| - 1$$

Since  $T$  is an integer we have  $|T| \geq |S|$ . Hence the Hall's condition holds. ■

Therefore permanent of  $\epsilon$ -approximate doubly stochastic matrix is also positive. Hence our algorithm for bipartite perfect matching is:

---

**Algorithm 27: BP-MATRIX-SCALING**

---

**Input:** Bipartite adjacency matrix  $A$  of  $G = (L \cup R, E)$   
**Output:** Decide if  $G$  has a perfect matching.

```

1 begin
2   while True do
3      $A \leftarrow$  Scale every rows of  $A$  to make it row stochastic.
4     if All column-sums are in  $(1 - \epsilon, 1 + \epsilon)$  then
5       return Yes
6      $A \leftarrow$  Scale every column of  $A$  to make it column stochastic.
7     if All row-sums are in  $(1 - \epsilon, 1 + \epsilon)$  then
8       return Yes

```

---

In both if conditions we are checking if the matrix is  $\epsilon$ -approximate doubly stochastic matrix. The moment it becomes a  $\epsilon$ -approximate doubly stochastic matrix we are done.

Now if  $G$  doesn't have a perfect matching then we will never reach a  $\epsilon$ -approximate doubly stochastic matrix since otherwise Hall's condition will hold and then we will have that the permanent is positive. So if  $G$  doesn't have a perfect matching the algorithm will run in an infinite loop. We only need to check if  $G$  has a perfect matching the algorithm returns Yes.

We will now define a potential function  $\Phi: \mathbb{Z}_0 \rightarrow \mathbb{R}_+$ . Let  $\sigma \in S_n$  such that  $a_{i,\sigma(i)} \neq 0$  for all  $i \in [n]$ . Now if an entry of the matrix is nonzero then it is always nonzero since all the entries are non-negative. Now since the scalings are symmetric we will define the potential function for  $i^{th}$  scaling (row/column) is  $\Phi(i) = \prod_{i=1}^n a_{i,\sigma(i)}$ . So we have  $\Phi(0) = 1$  since at first all the entries of the matrix are from  $\{0, 1\}$ . Also we know  $\Phi(t) \leq 1$  for all  $t$  since every time we are scaling the matrix. Now  $\Phi(1) \geq \frac{1}{n^n}$  since every row-sum can be at most  $n$  so it will be divided by  $n$  and therefore  $a_{i,\sigma(i)} \geq \frac{1}{n}$  for all  $i \in [n]$ . Now to show the while loop stops if  $G$  has a perfect matching it suffices to show that  $\Phi(t)$  increases by a multiplicative factor. So we have the following lemma.

**Lemma 13.1.9**

For all  $t$ ,  $\Phi(t+1) \geq \Phi(t)(1 + \alpha)$  for some  $\alpha \in (0, 1)$ .

**Proof:** Let  $A'$  denote the matrix at the  $t^{th}$  scaling where the  $(t-1)^{th}$  scaling was column-scaling. Let  $A''$  denote the matrix after row-scaling. Now since we went to the next iteration not all column-sums are in  $(1 - \epsilon, 1 + \epsilon)$  after scaling the rows. Now the row sums of  $A''$  are 1. Therefore we have

$$\frac{\Phi(t)}{\Phi(t+1)} = \prod_{i=1}^n Col-sum_i(A'') \leq \left( \frac{\sum_{i=1}^n Col-sum_i(A'')}{n} \right)^n = \left( \frac{\sum_{i=1}^n Row-sum_i(A'')}{n} \right)^n = 1 \implies \Phi(t) \leq \Phi(t+1)$$

Similarly we can say the same if  $(t-1)^{th}$  scaling was row-scaling. Since not all column-sums are in  $(1 - \epsilon, 1 + \epsilon)$  we have  $\sum_{i=1}^n (Col-sum_i(A'') - 1)^2 \geq \epsilon^2$ . Therefore using [Lemma 13.1.10](#) we have

$$\frac{\Phi(t)}{\Phi(t+1)} \leq 1 - \frac{\epsilon^2}{2} \implies \Phi(t+1) \geq \left(1 + \frac{\epsilon^2}{2}\right) \Phi(t)$$

Therefore we have the lemma. ■

We have  $\epsilon < \frac{1}{10n}$ . Therefore if  $t \geq 200n^4$  then we have

$$1 \geq \Phi(t) \geq \frac{1}{n^n} \left(1 + \frac{1}{200n^2}\right)^t \geq \frac{1}{n^n} e^{n^2} > 1$$

Hence the while loop will iterate for at most  $200n^4$  iterations. Hence this algorithm takes  $O(n^4)$  time. Hence if  $G$  has a perfect matching the algorithm runs for at most  $O(n^4)$  iterations. And if  $G$  doesn't have a perfect matching then the loop never stops. So we have the new modified algorithm to prevent infinite looping:

---

**Algorithm 28:** BP-MATRIX-SCALING
 

---

**Input:** Bipartite adjacency matrix  $A$  of  $G = (L \cup R, E)$   
**Output:** Decide if  $G$  has a perfect matching.

```

1 begin
2    $\epsilon \leftarrow \frac{1}{20n}$ 
3   for  $i \in [200n^4]$  do
4      $A \leftarrow$  Scale every rows of  $A$  to make it row stochastic.
5     if All column-sums are in  $(1 - \epsilon, 1 + \epsilon)$  then
6       return Yes
7      $A \leftarrow$  Scale every column of  $A$  to make it column stochastic.
8     if All row-sums are in  $(1 - \epsilon, 1 + \epsilon)$  then
9       return Yes

```

---

We will prove the helping lemma needed to prove [Lemma 13.1.9](#).

**Lemma 13.1.10**

Suppose  $x_1, \dots, x_n \geq 0$  and  $\sum_{i=1}^n x_i = n$  and  $\sum_{i=1}^n (1 - x_i)^2 \geq \delta$ . Then  $\prod_{i=1}^n x_i \leq 1 - \frac{\delta}{2} + o(\delta)$ .

**Proof:** Denote  $\rho_i = x_i - 1$ . So  $\sum_{i=1}^n \rho_i = 0$  and  $\sum_{i=1}^n \rho_i^2 \geq \delta$ . Now

$$\log(1 + \rho_i) = \sum_{j=1}^{\infty} (-1)^{j-1} \frac{\rho_i^j}{j} \implies \log(1 + \rho_i) \leq \rho_i - \frac{\rho_i^2}{3} + \frac{\rho_i^3}{3} \implies 1 + \rho_i \leq e^{\rho_i - \frac{\rho_i^2}{3} + \frac{\rho_i^3}{3}}$$

Therefore we have

$$\prod_{i=1}^n x_i \leq \exp \left[ \sum_{i=1}^n \rho_i - \sum_{i=1}^n \frac{\rho_i^2}{3} + \sum_{i=1}^n \frac{\rho_i^3}{3} \right] \leq \exp \left[ 0 - \frac{\delta}{3} + \frac{\left( \sum_{i=1}^n \rho_i^2 \right)^{\frac{3}{2}}}{3} \right] = \exp \left[ -\frac{\delta}{3} + \frac{\delta^{\frac{3}{2}}}{3} \right] \leq 1 - \frac{\delta}{2} + o(\delta)$$

Therefore we have the lemma. ■

There is also a survey, [\[Ide16\]](#) on use of matrix scaling in different results.

## 13.2 Matching in General Graphs

Here we give a similar algorithm for finding maximum matching in general graph as in the case of bipartite graphs in [subsection 13.1.2](#). We will give a similar characterization for the maximum matching in general graphs. First we will show an extension of berge's lemma to general graphs.

**Theorem 13.2.1**

For any graph  $G = (V, E)$ ,  $M \subseteq E$  is a maximal matching if and only if there is no augmenting paths in  $G$ .

**Proof:** Suppose  $M$  is a maximal matching. Then if  $G$  has an augmenting path  $p$ . Then we can just take the odd edges in  $p$  and then replace the edges in  $M \cap p$  with those edges i.e.  $M \Delta p$  and this is a larger matching than  $M$ . But this contradicts the maximum property of  $M$ . Hence  $G$  has no augmenting paths.

Now we will show that if  $M$  is not a maximum matching then  $G$  has an augmenting path. So suppose  $M$  is not a maximum matching. Let  $M'$  is a maximum matching. Then consider the graph  $G' = (V, E')$  where  $E' = M \Delta M'$ . Now every vertex in  $V$  has degree  $\in \{0, 1, 2\}$  in  $G'$ . Hence the connected components of  $G'$  are isolated vertices, paths and cycles. In a path or cycle the edges of  $M$  and  $M'$  not in both appear alternatively. Therefore the cycles are even cycles. Since  $|M'| > |M|$  there exists a path  $p$  such that number  $|p \cap M'| > |p \cap M|$ . Therefore the starting and ending edge of  $p$  are in  $M'$ . Hence  $p$  is an augmenting path in  $G$ . ■

Therefore like in the case of bipartite graphs we will search for augmenting paths in  $G$  for matching  $M$  and if we can find an augmenting path  $p$  we will update the matching by taking  $M' = M \Delta p$  and obtain a larger matching. But unlike bipartite graphs we can not run the same algorithm for finding augmenting paths as there can be edges between two odd layers or two even layers. So in the  $M$ -alternating tree there can be odd cycles but these odd cycles have all vertices except one vertex are matched using edges of the cycle. So we look for these special structures in the  $M$ -alternating tree called *blossom*.

### Definition 13.2.1: Blossom

A blossom is an odd cycle in which only one vertex is unmatched and the remaining vertices are matched using edges of the cycle. The exposed vertex is called the *base* of the blossom.

Note that given a matching  $M$  and blossom  $B$  we can modify  $M$  so that any  $v \in B$  is the base, since no vertex  $B$  has a matching outside.

The algorithm for finding augmenting path in non-bipartite graphs works by detecting blossoms in  $M$ -alternating tree starting from some exposed vertex. The idea is to then contract the blossoms into single vertex and then this process is repeated in the modified graph.

Let  $B$  be a blossom in  $G$ . Then the new graph is  $G' = (V', E')$  where

$$V' = (V \setminus B) \cup \{v_B\}, \quad E' = \left( E \setminus \{(u, v) : u \in B \text{ or } v \in B\} \right) \cup \{(u, v_B) : u \notin B, v \in B, (u, v) \in E\}$$

**Observation 13.5.**  $v_B$  is an exposed vertex in  $G'$

For this first time we have to show that finding augmenting path in the contracted graph gives an augmenting path in original graph and vice versa.

### Lemma 13.2.2

$G = (V, E)$  is a graph with matching  $M \subseteq E$  and a blossom  $B$ . Let  $G' = (V', E')$  be the contracted graph after contracting  $B$  into a single vertex  $v_B$ . Then  $G$  with matching  $M$  has an augmenting path if and only if  $G'$  with matching  $M' = M \setminus \{(u, v) : u, v \in B\}$  has an augmenting path

**Proof:** Let  $p$  be an augmenting path in  $G$ . Let  $p = (v_0, \dots, v_k)$  where both  $v_0$  and  $v_k$  are exposed vertices. Hence at least one of  $v_0$  and  $v_k$  are not in  $B$ . WLOG  $v_0 \notin B$ . If none of the vertices in  $p$  are in  $B$  then  $p$  also exists in  $G'$  as well. Therefore  $G'$  has an augmenting path. So suppose  $p \cap B \neq \emptyset$ . Suppose  $v_r$  be the first vertex in  $p$  that is in  $B$ . Then  $p' = (v_0, \dots, v_{r-1}, v_B)$  is an augmenting path since  $v_B$  is an exposed vertex in  $G'$ .

Now let  $p'$  is an augmenting path in  $G'$ . If  $v_B$  is not in  $p'$  then  $p'$  also exists in  $G$ . Therefore  $p'$  is an augmenting path in  $G$ . Suppose  $v_B$  is in  $p'$ . ■

# Linear Programming

## 14.1 Introduction

### Definition 14.1.1: Linear Program

A linear programming problem asks for a vector  $x \in \mathbb{R}^d$  that maximizes or minimizes a given linear function, among all vectors  $x$  that satisfy given set of linear inequalities.

The general form of a maximization linear programming problem is the following: given  $c \in \mathbb{R}^n$ ,  $b \in \mathbb{R}^m$ ,  $a_i \in \mathbb{R}^n$  for each  $i \in [m]$  then

$$\begin{aligned} & \text{maximize} && c^T x \\ & \text{subject to} && a_i^T x \leq b_i \quad \forall i \in [p], \\ & && a_i^T x = b_i \quad \forall i \in \{p+1, \dots, p+q\}, \\ & && a_i^T x \geq b_i \quad \forall i \in \{p+q+1, \dots, m\}, \\ & && x_j \geq 0 \quad \forall j \in [k], \\ & && x_j \leq 0 \quad \forall j \in \{k+1, \dots, k+l\} \quad (\text{Some } x_j \text{'s are free}) \end{aligned}$$

The similar goes for minimization linear programming problem. For maximization problem we can always write the LP in the form

$$\begin{aligned} & \text{maximize} && c^T \hat{x} \\ & \text{subject to} && \hat{a}_i^T x \leq b'_i \quad \forall i \in [m], \\ & && x'_j \geq 0 \quad \forall j \in [n] \end{aligned}$$

And then the LP is said to be in the **canonical form**. What we can do is the following:

- For  $i \in \{p+q+1, \dots, m\}$ , we can replace  $a_i^T x \leq b_i$  with  $-a_i^T x \geq -b_i$
- For  $i \in \{p+1, \dots, p+q\}$ , we can replace with two constraints  $a_i^T x \geq b_i$  and  $a_i^T x \leq b_i$
- For  $j \in \{k+1, \dots, k+l\}$ , we can replace  $x_j \leq 0$  with  $-x_j \geq 0$
- For  $j \in \{k+l+1, \dots, n\}$ , we can replace the free  $x_j$ 's with  $x_j^+ - x_j^-$  all the equations where  $x_j^+, x_j^- \geq 0$

This way we can always get a LP of that form. Now we can replace the  $\hat{a}_i$  for  $i \in [m]$  with a matrix  $A \in \mathbb{R}^{m \times n}$  and replace the constraint  $\hat{a}_i^T x \leq b'_i, \forall i \in [m]$  with  $Ax \leq b$

$$\begin{array}{ll} \text{maximize} & c^T x \\ \text{subject to} & Ax \leq b, \\ & x \geq 0 \end{array} \qquad \begin{array}{ll} \text{minimize} & c^T x \\ \text{subject to} & Ax \geq b, \\ & x \geq 0 \end{array}$$

## 14.2 Geometry of LP

### Definition 14.2.1: Feasible Point and Region

A point  $x \in \mathbb{R}^n$  is *feasible* with respect to some LP if it satisfies all the linear constraints. The set of all feasible points is called the *feasible region* for that LP.

Feasible region of a LP has a particularly nice geometric structure. Before that we will first introduce some geometric terminologies used in the linear programming context:

### Definition 14.2.2: Hyperplane, Polyhedron, Polytope

- **Line:** The set  $\{x + \lambda d, \lambda \in \mathbb{R}\}$  is line for any  $x, d \in \mathbb{R}^n$ .
- **Hyperplane:** The set  $\{x \in \mathbb{R}^n : a^x = b\}$  is a hyperplane for any  $a \in \mathbb{R}^n$  and  $b \in \mathbb{R}$ .
- **Hyperspace:** The set  $\{x \in \mathbb{R}^n : a^x \leq b\}$  is a hyperspace or half-space for any  $a \in \mathbb{R}^n$  and  $b \in \mathbb{R}$ .
- **Polyhedron:** A polyhedron is the intersection of a finite set of half-spaces i.e. the set  $\{x \in \mathbb{R}^n : Ax \leq b\}$  for any  $A \in \mathbb{R}^{n \times m}$ ,  $b \in \mathbb{R}^m$ .
- **Polytope:** A bounded polyhedron is called a polytope.

Now it is not hard to verify that any polyhedron is a convex set i.e. if a polyhedron contains two points then it contains the entire line segment joining those two points.

#### Lemma 14.2.1

Polyhedron is a convex set

Hence the feasible region of a LP creates a polyhedron in  $\mathbb{R}^n$ . And  $c^T x$  is the hyperplane normal to the vector  $c$  and the objective of the LP is by moving the plane normal to the vector  $c$  for which point in the polyhedron the hyperplane  $c^T x$  has the highest value. Since polyhedron can be unbounded there may not exist any point  $x$  where  $c^T x$  is maximum.

Suppose we have a LP

$$\begin{aligned} & \text{maximize} && c^T x \\ & \text{subject to} && Ax \leq b, \\ & && x \geq 0 \end{aligned}$$

Let  $P$  be the polyhedron  $P = \{x \in \mathbb{R}^n : Ax \leq b\}$ . Then given  $x^* \in P$  if any constraint  $a_i^T x^* = b_i$  then this constraint is said to be *tight* or *binding* or *active* at  $x^*$ . Now two constraints  $a_i^T x \leq b_i$  and  $a_j^T x \leq b_j$  are said to be linearly independent if  $a_i$  and  $a_j$  are linearly independent.

### Definition 14.2.3: Basic Solution and Basic Feasible Solution

$x^* \in \mathbb{R}^n$  is a basic solution if  $n$  linearly independent constraints are active at  $x^*$  (Doesn't need to be feasible).

$x^* \in \mathbb{R}^n$  is a basic feasible solution if  $x^*$  is a basic solution and  $x^* \in P$ . The basic feasible solutions are also called *corners* of a polyhedron.

#### Theorem 14.2.2

Given a LP

$$\begin{aligned} & \text{minimize} && c^T x \\ & \text{subject to} && Ax \geq b, \\ & && x \geq 0 \end{aligned}$$

Let  $P$  is the polyhedron  $\{x \in \mathbb{R}^n : Ax \leq b, x \geq 0\}$ . Suppose  $P$  is non-empty and has at least one basic feasible

solution then either the optimal value is  $-\infty$  or there is an optimal basic feasible solution.

### Theorem 14.2.3

If polyhedron  $P$  does not contain a line it contains at least one basic feasible solution (Hence if  $P$  is bounded it contains at least one basic feasible solution).

With this geometry in hand, we can easily picture two pathological cases where a given linear programming problem has no solution. The first possibility is that there are no feasible points; in this case the problem is called *infeasible*. The second possibility is that there are feasible points at which the objective function is arbitrarily large; in this case, we call the problem *unbounded*. The same polyhedron could be unbounded for some objective functions but not others, or it could be unbounded for every objective function.

### Example 14.2.1

- **Maximum Matchings:** Given undirected graph  $G = (V, E)$ . Say variable  $x_e$  for each  $e \in E$ ,  $x_e = 1 \implies e$  in matching and  $x_e = 0$  otherwise.

$$\begin{aligned} & \text{maximize} && \sum_{e \in E} x_e \\ & \text{subject to} && \sum_{e \text{ incident on } v} x_e \leq 1 \quad \forall v \in V, \\ & && x_e \geq 0 \quad \forall e \in E, \\ & && x_e \in \{0, 1\} \quad \forall e \in E \end{aligned}$$

**Observation.**  $M$  is a matching iff  $\{x: x_e = 1 \text{ if } e \in M, = 0 \text{ otherwise}\}$  is a feasible solution

- **Maximum  $s - t$  Flow:** Given directed graph  $G = (V, E)$  with vertices  $s, t$  and capacity  $c_e$  on edges. Say variable  $x_e$  for each edge and equal to flow on that edge. Then the LP of this problem:

$$\begin{aligned} & \text{maximize} && \sum_{e \in \text{out}(s)} x_e \\ & \text{subject to} && \sum_{e \in \text{in}(v)} x_e - \sum_{e \in \text{out}(v)} x_e = 0 \quad \forall v \in V, v \neq s, t, \\ & && c_e \geq x_e \geq 0 \quad \forall e \in E \end{aligned}$$

We will now introduce a theorem without proof that for any LP with a polytope we can find a solution in polynomial time.

### Theorem 14.2.4

Let  $P = \{x \in \mathbb{R}^n: Ax \geq b\}$  be a polytope. Then we can find an optimal basic feasible solution for the LP  $\min c^T x$  where  $x \in P$  in polynomial time.

## 14.3 LP Integrality

For the LP for matchings in bipartite graphs  $G = (L \cup R, E)$  we have:

$$\begin{aligned} & \text{maximize} && \sum_{e \in E} x_e \\ & \text{subject to} && \sum_{e \text{ incident on } v} x_e \leq 1 \quad \forall v \in V, \\ & && x_e \geq 0 \quad \forall e \in E \end{aligned}$$

We want  $x_e \in \{0, 1\}$  i.e. we want to have integral solution for this LP

### Question 14.1

LP's can give fractional solutions. When is solution integral?

Sufficient Condition: Every basic feasible solution of the feasible polytope is integral i.e.  $x^*$  is basic feasible solution  $\Rightarrow x^* \in \mathbb{Z}^n$ . If all basic feasible solution are integral then for all  $I \subseteq [m]$  with  $|I| = n$ ,  $A_I^{-1}b_I$  is integral. Let  $x = A_I^{-1}b_I$ . Then  $j^{th}$  component  $x_j = \frac{|A_I^j|}{|A|}$  (Cramer's Rule).

### 14.3.1 Totally Unimodular Matrix

#### Definition 14.3.1: Totally Unimodular Matrix (TUM)

A matrix  $A \in \{0, 1, -1\}^{m \times n}$  is totally unimodular (TU) if every square submatrix of  $A$  has determinant  $-1, 0, 1$ .

Hence in the above LP is  $A$  is TU and  $b$  is integral then all basic feasible solutions are integral.

#### Lemma 14.3.1

Let  $A$  be TUM and  $b \in \mathbb{Z}^n$  then  $P = \{x: Ax \geq b\}$  is integral i.e. every basic feasible solution is integral.

Hence using Theorem 14.2.4 if the polytope is integral we can find optimal integral solution in polynomial time. We will now discuss properties of Totally Unimodular Matrix.

#### Lemma 14.3.2

$A \in \{0, 1, -1\}^{m \times n}$  is TU iff the following are TU:

- (i)  $-A$
- (ii)  $A^T$
- (iii)  $[A \ e_i], [A \ -e_i]$
- (iv)  $[A \ I], [A \ -I]$
- (v)  $[A \ A_i], [A \ -A_i]$  where  $A_i$  is the  $i^{th}$  column of  $A$ .

#### Corollary 14.3.3

If  $A$  is TUM and  $a, b, c, d \in \mathbb{Z}^n$  are integer vectors then the polytope  $Q = \{x \in \mathbb{R}^n: a \leq Ax \leq b, c \leq x \leq d\}$  is integral.

**Proof:** We can combine the four inequalities in one inequality. Consider the matrix  $[A \ -A \ I \ -I]^T$ . Then the given polytope is

$$Q = \left\{ x \in \mathbb{Z}^n: \begin{bmatrix} A \\ -A \\ I \\ -I \end{bmatrix} x \leq \begin{bmatrix} b \\ -a \\ d \\ -c \end{bmatrix} \right\}$$

By Lemma 14.3.2,  $[A \ -A \ I \ -I]^T$  is a TUM since  $A$  is TUM. Therefore the polytope  $Q$  is integral. ■

The following theorem lets us to give a necessary and sufficient condition to check if a given matrix is TUM. Again we will accept the following theorem without the proof since the proof is a little nontrivial.

**Theorem 14.3.4**

Let  $A \in \{-1, 0, 1\}^{m \times n}$ . Then  $A$  is TU iff every set  $S \subseteq [n]$  can be partitioned into  $S_1, S_2$  such that

$$\sum_{i \in S_1} A_i - \sum_{i \in S_2} A_i \in \{-1, 0, 1\}^m$$

where  $A_i$  is the  $i^{\text{th}}$  column of  $A$ .  $\square$

Now using this theorem we will show that the polytope for bipartite maximum matching is integral.
